The Goulstonian Lectures

ON

SOME DISORDERS OF THE CEREBRAL CIRCULATION AND THEIR CLINICAL MANIFESTATIONS.

livered before the Royal College of Physicians of London on March 11th, 16th, and 18th, 1909,

By ALFRED E. RUSSELL, M.D. Lond., F.R.C.P. Lond.,

PHYSICIAN TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

LECTURE I.

Delivered on March 11th.

DIMINUTION OF THE BLOOD-SUPPLY TO THE BRAIN.

Syncopal Attacks.

IR. PRESIDENT AND GENTLEMEN,—The fundamental or in the pathology of a fainting fit is a diminution in the ume of blood passing through the brain. Sir William vers suggests that the resulting diminution of the intra- nial pressure may be an important factor in the loss of sciousness. The causes of an attack of fainting are nerous; but we are concerned here, however, with syncopal icks occurring apart from gross organic disease. Such y be precipitated by very different causes, sudden shock, excitement, the sight of a street accident, the sight of od, a hot room, hunger, and so on. Many people are very ne to such attacks and this tendency to faint on slight vocation is apt to run in families.

'hysiologically two important factors are concerned: , vaso-dilatation in the splanchnic area, and secondly diac inhibition. It is probable that in some cases one only these factors is primarily concerned; in others both may nvolved. Some people never faint in the whole of their ; in others one isolated attack occurs; others are very ne to it on slight provocation. It is certain that many ple display an instability of the vaso-motor system apart n any emotional state, although emotion may be, and en is, very potent in that direction.

. Solis Cohen has studied this question.[1] He proposed term vaso-motor ataxia for a "condition of instability [illegible] certain persons, [illegible] disturbance with [illegible] of the cardio- [illegible] most strikingly played by the heart and by the peripheral vessels of the remities, but analogy indicates the occurrence of similar nomena in the ve [illegible] re especially in the [illegible] t, and of the br [illegible] eously, but often [illegible] ong the influence [illegible] ecially cold; toxic agents formed in the body or intro- ed from without; visceral or internal reflex excitation; l emotion." The vascular phenomena include functional rt disturbances, vaso-dilatation, and vaso-constriction. rbid alterations in the thyroid are not uncommon. He ards dermographism as an essential feature of the dition and claims the existence of a hæmorrhagic dency as shown by ecchymoses, petechiæ, epistaxis, noptysis, hæmatemesis, hæmaturia, and retinal hæmor- ge. He enumerates a very large number of allied morbid ociations and among them hysteria, urticaria, local ema, asthma, vertigo, migraine, epilepsy, neurasthenia, rotic dyspepsia, membranous enteritis, &c. Doubtless ny would hesitate to accept Solis Cohen's scheme in its irety, but it does gather together a series of conditions, ny of which are not infrequently found in combination. are familiar with cases presenting irregular circulatory nifestations, such as blue hands, cold extremities, lblains, palpitation, flushings, &c., often associated with graine, neurasthenia, dyspepsia, and so forth. Such individuals are rarely robust and in many of them, moreover, there is a marked tendency to faint on slight provocation. Solis Cohen does not include this in his large list of clinical manifestations, but vaso-motor and cardiac instability are very prominent features in many people of fainting tendencies. Their vascular mechanism is often unable to adjust itself to the slightest strain, as seen in the momentary faintness on getting up from a stooping position.

A sudden depression of the normal vaso-motor tone in the splanchnic area leads to a rapid accumulation of blood in the capacious vessels of that region; if only momentary in duration the result is merely the sudden sinking at the pit of the stomach—so common after any unexpected noise or fright. If of longer duration this preliminary sensation or aura is succeeded by a faint. The rapidity of onset of a faint depends on the nature of the cause and is proportional to the rapidity with which the vaso-motor control of the splanchnic area is lost. Fatigue or a hot room is often associated with a very gradual development of an attack, and doubtless with a slowly increasing splanchnic change. The removal of the cause will often cut short the attack before unconsciousness supervenes. A sudden shock, however, may cause almost sudden unconsciousness; and doubtless very sudden vaso-dilatation can occur. It is difficult to judge as to the degree and frequency with which the heart may be affected independent of the change in the splanchnic area. The feeble pulse is scarcely a criterion to go by in the presence of the fall in blood pressure due to the abdominal vaso-dilatation and of the small volume of blood available for the circulation. It would seem probable, however, that in some cases direct cardiac inhibition does occur. The two factors might also be brought into action simultaneously.

Attacks characterised by Cardiac and Vaso-motor Symptoms with Modification rather than Loss of Consciousness.

Attention has been drawn of late to a type of attack in which vagal and vaso-motor symptoms are prominent and in which consciousness though modified is not of necessity lost. Gowers describes a series of such cases under the title of "Vagal and Vaso-vagal Attacks."[2] The onset is commonly sudden. The salient features are cardiac and vaso-motor with some modification of consciousness in the large majority of cases. There is obvious vaso-constriction of the cutaneous vessels in the majority of cases—as evidenced by pallor of face, coldness of extremities, and tingling. Coldness of the extremities was noted in eight of Gowers's 11 cases. It was present in a marked degree in two of my own. Pricking and numb feelings of hands and feet occur, and are probably also the result of vaso-constriction. They are common in the extremities in gross arterial disease.

The feeling of suffocation and the orthopnœa noticed in several of Gowers's cases are very interesting. Their nature is obscure but it may well be that they are pulmonary in origin. The [illegible] and Brodie[3] [illegible] the systemic [illegible] of blood contained in the pulmonary vessels. These cases exhibit obvious changes both in the cardiac and systemic systems. Vaso-dilatation in the splanchnic area is almost beyond dispute in many of the cases, although we cannot directly inspect the splanchnic vessels. The distribution of blood is disorganised over the whole body and engorgement of the pulmonary vessels is very possible, and in cases in which it occurred would be a feasible explanation of the dyspnœa observed. Bronchial spasm may possibly participate in its causation.

Splanchnic dilatation is suggested directly by the disappearance of the blood from the cutaneous surface, factors of very common concurrence, and also by the copious diuresis following the attack in some cases. Rapid and rather persistent splanchnic vaso-dilatation is evidently a very important factor in these cases.

[illegible] the order of sequence d[illegible] of the vascular area p[illegible] of the vascular crisis. An initial splanchnic vaso-dilatation with lowered blood pressure would clearly explain some cases. A severe initial vaso-constriction, for instance, in the extremities, with rise of blood pressure, may possibly occur in some cases of so-called

Vaso-motor Ataxia, American Journal of the Medical Sciences, 1894, cvii., p. 130.

[2] The Borderland of Epilepsy, p. 18, et seq.

[3] Lectures on the Pulmonary Circulation, The Lancet, March 22nd, 1902, p. 803.

vaso-motor angina, though James Mackenzie found that the blood pressure was not raised in some cases he had the opportunity of examining in an attack. Sir R. Douglas Powell, in his article on this subject in Allbutt's System of Medicine, notes the same cardio-vascular instability and the same physical and mental relationships. James Mackenzie discusses the subject under the very non-committal title of the x disease.[4] Pal has ably demonstrated the importance of vascular changes in relation to clinical symptoms in an exhaustive monograph.

It is difficult to decide in each case whether the coldness of the skin is due to active vaso-constriction, or whether the skin vessels are merely narrowed down just enough to accommodate the diminished amount of blood available for them.

In some of the cases consciousness has been modified—a dreamy mental state may be present and a feeling of impending death is not uncommon. The extreme weakness of the pulse indicates a vascular depression that must of necessity affect the brain, and we know too little of the nature of mental processes to predict what alteration should attend a diminished blood flow. Momentary loss of consciousness occurs occasionally, as in some of Gowers's cases, and when it occurs he regards it as epileptic in nature—as *petit mal.* The unconsciousness may be an early or a late symptom in the attack and in my opinion simply represents the fact that when it occurs the vascular depression has reached a point incompatible with consciousness. Cerebral vaso-constriction may account for it in some cases, cardiac inhibition with low blood pressure in others. Further, the prolonged symptoms in these cases are often of a type which, if of momentary duration, would be fairly characteristic epileptic auræ. At the same time, as has been pointed out, many of them are obviously vaso-motor or cardiac in origin and that this is recognisable is due to the fact that they are exceedingly deliberate in onset instead of sudden. If they were of slightly shorter duration and of greater intensity the epileptic relationship of these cases would be still clearer. Gowers, of course, recognises that many of these cases present distinctly epileptic phenomena, and remarks also that "velocity is an essential element of ordinary epilepsy, but this does not preclude the possibility of deliberation in attacks not far removed from epilepsy." I have seen four such cases and they are doubtless commoner than is suspected, their somewhat indeterminate character and the absence of symptoms between the attacks rendering them difficult of recognition.

THE SUDDENNESS OF SOME FAINTS.

Whilst the onset of an ordinary faint is gradual, in some cases it is rapid and may be absolutely sudden. A man very subject to ordinary faints on one occasion suffered from a sudden attack; he was sitting down and feeling perfectly well when he fell absolutely suddenly and bruised his face on the ground. Gowers also remarks that those who are prone to faint become after a time liable to do so more suddenly. In such cases there can be no question as to the nature of the attack. The vascular depression responsible for the ordinary faint must have occurred with greater rapidity. The suddenness suggests that a very transient and sudden cardiac inhibition occurred rather than that the attack was due to splanchnic vaso-dilatation. An isolated attack of unconsciousness sometimes with muscular spasm is not an unknown event in people showing no other signs of any tendency to faints or fits. Sudden cardiac inhibition supplies the most likely explanation of these attacks.

THE CONVERSION OF FAINTING FITS INTO EPILEPTIC FITS.

Gowers has recorded cases in which repeated syncopal attacks have passed into epilepsy.[5] Thus:—

> A girl when about seven years old became liable to faint on any sudden start or alarm. The faints had all the character of cardiac syncope; there were pallor, coldness, and gradual loss of consciousness After some years such faints occurred without exciting cause, and became more sudden in onset. When she was 17 years old one of these attacks passed into a distinct epileptic fit, with deviation of the head, general clonic spasm, and micturition during the attack. Others followed.

Gowers quotes two other cases. In all three the same phenomena were presented: attacks originally brought on by external influences and typically syncopal, after a lapse of time appeared spontaneously and with a more sudden onset—in fact, becoming undoubtedly epileptic. The explanation of change that naturally suggests itself is that the incr suddenness of the attacks is due to an increase in the rapi with which the circulatory changes are brought about.

The symptoms of syncope are certainly due to car vascular changes with alteration in the cerebral circulat and an increase in the velocity of change would fully acc for the suddenness of the unconsciousness. Gowers, h ever, postulates a change in the nerve elements of the b as underlying the loss of consciousness in syncope, produ not directly by the failure of the circulation but rather a sudden diminution in the intracranial pressure resul from the circulatory failure. He also states that "we h to conceive it"—i.e., a change in the nerve elements— occurring spontaneously in epilepsy and as due to a sud diminution in the intracranial pressure in syncope," further that these cases in which repeated syncope seem pass into minor epilepsy "suggest that the state of the n elements that underlies the loss of consciousness in sync may, by repeated induction, acquire a tendency to sp taneous development, which constitutes minor epilepsy."

I submit that by frequent repetition the "resistance the nervous mechanism of the cardio-vascular apparat diminished, the reflex becomes easier, and the failure of circulation occurs with greater rapidity, with the result the loss of consciousness is proportionally more sudden. distinction is one of the greatest importance, for the view assumes a suddenly developing, mysterious state of nervous system in which it becomes liable to sudden ca less failures of its activity, causeless in the sense that t are now independent of the circulatory failure admitt producing the earlier attacks, whilst the other view aff an explanation of these attacks more in accordance their clinical history.

So far we have considered, firstly, the ordinary fainting We have seen that definite subjective sensations or a may attend its onset, that it is often associated with v motor instability, that it may be very sudden in onset inst of gradual, and, finally, that it may change in type become distinctly epileptic in character. In other group cases we have seen marked cardiac and vascular instabi with the development of a series of symptoms depend directly on these cardiac and vaso-motor changes. M of these ~~symptoms are identical with epileptic auræ~~ tho more prolonged. We have seen that consciousness ma preserved though modified, that it may almost vanish, a finally, that unconsciousness may develop. In all th cases the pathological variations in the circulation are s as to fully account for the unconsciousness and for epileptic character of some of them.

The phenomena attending a sudden transient and dem strable arrest of the heart should afford valuable evidenc regards the influence of sudden cerebral anæmia in the p duction of symptoms These phenomena can be studied cases of heart block.

CESSATION OF THE CEREBRAL CIRCULATION.—SUDDE AND TRANSIENT.

(*a*) *Heart Block.*

Alfred Webster[6] records a case accompanied by a se of 60 beautiful sphygmographic tracings which estab beyond question the fact that arrest of the heart prece the epileptiform attacks. Another most instructive case recorded by Finny.[7] The patient was a woman, aged years, who suffered from bradycardia and arryhthmia of heart. Without entering into any details as to the car condition it may be stated that the pulse rate was, as a r between 21 and 28 per minute. At varying intervals, h ever, the rate changed and a state of pulselessness las from five to 15 seconds supervened. During these la periods certain fits, or, as she described them, "weak tur developed. Frequent observations determined the fact the fits were sure to occur when pauses of eight to 10 o seconds were observed, and that they occurred towards end of the period of cardiac asystole. Finny gives following description of the fits:—

> A "weak turn" was ushered in and preceded by a delay in heart's beat and radial pulse. Thus, when a pause lasted seven to

hibitory powers can be obtained. This method has been lopted in the following experiments and the encouraging sults that it has yielded have induced me to publish this reliminary account of observations on tuberculosis in the ope that it may attract other workers to contribute the rge number of results that will be necessary before what romises to be a new chapter in pathology can be established n a firm basis. The method used for estimating the elec-ical conductivity of the solutions was that of Kolrausch ith the rapidly alternating current and telephone.

The vessels used were after the pattern of those of Henri, aving a capacity of 15 cubic centimetres. To permit of ady cleansing it is important that they should be wide-outhed and stoppered to prevent evaporation. The resist-nce capacity of the vessels was redetermined at intervals ith $\frac{n}{10}$ KCl and the electrodes replatinised from time to me. The digestion took place in a thermostat kept at 4° C. The substrate used was 2·5 per cent. solution f sodium caseinogenate to which ammonia was added the proportion of 1 cubic centimetre of 0·880 mmonia to a litre of the casein solution. Although ot more than 0·2 cubic centimetre of serum is required or a determination, it has been the practice in these xperiments to use much larger quantities in order, as ar as possible, to eliminate errors due to the measurement f very small quantities. It is possible to obtain without [illegible] of blood from a puncture in [illegible] int of a cataract knife, but the [illegible] gated have been bled by punc-[illegible] with a small sterilised syringe. [illegible] gainst this procedure is quite nwarranted. I have personally experienced it about 200 imes without the smallest inconvenience or appearance of carring or thickening over the median basilic. It is perfectly ainless when properly done with a sharp needle, and atients generally prefer it to withdrawing blood by rdinary puncture of the finger as being more rapid and ss uncomfortable. If the skin is first sterilised and the atient requested to look in another direction the whole peration is conducted without any trouble; the application f dressing afterwards is unnecessary and alarming. It is [illegible] seconds after [illegible] of blood. [illegible] a firm clot has [illegible] kept in an ice chest. There is some evidence [illegible] serum left in contact with the [illegible] probably from the setting free [illegible] es by the disintegrating leuco-ytes. I have been unable to find any evidence of diminu-ion of antitryptic activity in aseptic serum kept in the cold or many days. As a convenient unit of conductivity the eciprocal megohm or gemmho, as introduced by Waller, nay be used. Asepticity is secured by the presence of ormalin, 5 cubic centimetres of 5 per cent. formol being dded to every litre of the stock casein solution. The ormalin itself has a slight inhibitory action on tryptic ctivity.

In an actual experiment the following technique was bserved. The conductivity vessels each received 10 cubic entimetres of casein solution and to this the serum was dded. The serum and substrate were now allowed to [illegible] mostat and an appropriate [illegible] The trypsin degenerates [illegible] olution that it was deemed xpedient to always add the measured pipetteful of trypsin in he cold state, as in the measuring of the ferment into a [illegible] for an appre-[illegible] state to take [illegible] ten minutes efore the first reading of [illegible] lummy experiments having [illegible] oom temperature equal to [illegible] dded to the casein-charged vessel took 7·5 minutes to each the mean temperature of the thermostat. The eadings were afterwards made at regular intervals of 15 ninutes. Duplicate vessels were used, so that in every case he mean of two readings was obtained. A point to which [illegible] the agitation of each vessel while [illegible] g run in from the pipette, other-[illegible] obtained which can be accounted or by the possible combination of enzyme and casein [illegible]

[illegible] was only determined upon after a series of [illegible] the two enzymes which reveale[illegible] ction of serum [illegible] a pro-gressive loss of inhibitory power [illegible] out the course of the reaction is one that has to be considered. Bayliss showed that when sufficient serum was added to a trypsin solution to completely prevent its attacking the caseinogen for at least two days, the caseinogen is slowly [illegible] may become a straight line with an [illegible] that the antitryptic [illegible], as had been pre-viously shown to be the case by [illegible] for the antitrypsin of intestinal worms. Using the small quantities of serum that [illegible] found evidence [illegible] serum which has been first mixed with trypsin and [illegible] n added to the caseinogen solution curves have occasionally occurred resembling those described by Bayliss. As such curves are not obtained when the serum is first diluted by mixing with the casein, and the trypsin is then added to the casein and serum mixture and the whole shaken, it would appear that we have to deal with a condition of absorption of the trypsin by the serum, which is then slowly liberated, and that this phenomenon does not tend to occur in cases in which the serum is already diluted. The question does not, at any rate, arise in connexion with the small quantities of serum used.

The curves obtained, as shown in Fig. 1, representing the quantity of casein converted and time, fall off continuously throughout the experiment from the logarithmic curve, the velocity constant decreasing in value as the end-point is approached. The form of the curve which tends to become

attack only lasted two days but in the act of vomiting and retching he felt "something suddenly give way in the chest. Shortly afterwards pain was felt in the left chest and his breathing became difficult." In consequence of this he gave up his appointment in America and coming to London he became an in-patient of Charing Cross Hospital. With rest and treatment he recovered sufficiently to be able to take up work again, and he continued working for a period of 15 months. At the end of this period as he was not feeling well he took a rest for six weeks, when he was again able to resume his duties which he discharged for six months.

When the patient came under my care he was the subject of difficulty of breathing of an intermittent character which was always worst at night. The arterial tension as estimated by the Riva-Rocci apparatus was equal to 180 millimetres of mercury. The radial pulse, which was rapid and irregular, was equal on both sides. Cardiac dulness commenced in the line of the left nipple and was carried to the right border of the sternum. Over the base of the heart the second sound was accentuated, while over the apex area the first sound was murmurish, feeble, and often indistinct. No apex beat could be felt. Owing to the difficulty of breathing the patient, especially at night, frequently occupied the semi-upright position. Beyond the signs of slight pulmonary emphysema and the presence of a certain amount of dulness over the base of the left chest posteriorly and in the axillary region nothing abnormal was detected on percussion. The respiratory murmur was coarse over the upper part of each lung, while over each base crepitation was heard. The urine had a specific gravity of 1025 and 22 ounces were passed daily; it contained a large quantity of albumin. The abdomen presented nothing abnormal. There was no œdema of the feet. The attacks of difficulty of breathing were relieved by inhalations of nitrite of amyl.

Three weeks after his admission into the infirmary the patient began to spit up blood apparently from the left lung. The breathing became Cheyne-Stokes in character, the periods of apnœa lasting frequently from 40 to 60 seconds. [illegible] ix ounces daily and contained blood. Five [illegible] sodium acetate were administered every [illegible] hours and within 12 hours the urine rose to 84 ounces [illegible] the following day to 96 ounces. For several nights [illegible] patient slept better; he seemed much improved and the bleeding from the lungs and the kidneys entirely ceased. The improvement only lasted a short while, for the patient was suddenly seized with acute pain over the right side of the chest. Over the affected area friction could be heard. The dulness over the base of the left lung increased and the respiratory murmur became almost inaudible. By degrees the quantity of urine diminished, the breathing became again difficult, and the pulse and the heart sounds feebler. The patient died exactly one month after his admission into the infirmary.

For the following notes of the post-mortem examination I am indebted to Dr. George Hall, pathologist to the Royal Victoria Infirmary:—

There is no œdema of the extremities. The pericardium contains a small quantity of free fluid. The left pleural cavity contains about two pints of fluid, in consequence of which the lower lobe of the lung [illegible] chest shows signs of recent pleurisy. In [illegible] mentioned the lungs are œdematous at the [illegible] are emphysematous. The heart is large. The p[illegible] ventricle is thickened. The mitral [illegible] its cusps are normal. The cavity [illegible] and its walls considerably thicke[illegible] several fatty and atheromatous patches, between which are interspersed calcareous plates About one inch above the valve, the cusps of which are healthy, there is a well defined aneurysmal dilatation of the vessel which extends almost to the origin of the left carotid and subclavian arteries, while beyond this there is at the commencement of the descending aorta a fusiform dilatation of the vessel. The main aneurysm which is saccular has a definite daughter saccule nearly the size of a golf ball springing from its anterior surface and pointing forwards. The dilatation of the aorta extends to the root of the innominate artery but not into the vessels arising from it. The interior of the aneurysm is occupied by firm decolourised clot but this does not extend *into the innominate artery to block it. At places the* [illegible] the wall of the aorta. A careful examination [illegible] to detect any involvement of nerves in [illegible] orifice admits the tips of five fingers. The pulmonary artery and valves are healthy. Liver and spleen [illegible] The right is small and contains a [illegible] le on being stripped off leaves a [illegible] the cortex is thin and pale and shows similar changes to those [illegible] described as pale contracting kidneys.

Whatever may be our opinion in regard to the gr[illegible] thoracic aneurysm it is within the experience of physi that patients who are the subjects of this affection ma only live a considerable time after their malady has detected but that even alarming and distressing [illegible] may temporarily subside or even entirely disappear. I does not always come by rupture of the sac, threate at times as this may seem. Where improvement has t place for a period and the patient has subsequ succumbed to an intercurrent malady, the aneurysm a necropsy is frequently found to have been undergoi process of cure, nature's method of accomplishing being the strengthening of the walls of the sac by internal deposition of layer after layer of clot which dimini the shock imparted to the sac by each systole of the ventricle. While such a deposition of fibrin occur aneurysms situated at some distance from the heart occasionally leads to spontaneous cure it is maintaine some pathologists that the conditions of quietude, low arterial tension, and slowing of the circulation, which essential to the formation of clot within an aneurysmal are almost impossible when the aneurysm is near the he for example, on the ascending portion of the arch of aorta. Notwithstanding all these it is yet a fact that large number of cases of thoracic aneurysm, espec of the sacculated type, clot is found in the inte indicating an effort on the part of nature to establi cure.

The presence or absence of coexisting aortic regurgita is not without importance in regard to the depositio fibrin in thoracic aneurysm. If there is aortic incompet of any severity there can hardly be in the interior thoracic aneurysmal sac the same favourable condition clotting likely to appertain where there is no a reflux, for in uncomplicated cases of thoracic aneur the left ventricle of the heart is usually not hy trophied to any extent, if at all, while it is enlarged aortic regurgitation. The fact that patients occasion live for several years after their thoracic aneurysm been detected can only be explained by the prese of the firm clot in the interior of the sac observed a death.

A few of my own pati[illegible] aneurysm lived seven or eig[illegible] case longer, after first coming [illegible], others several months, notwithstanding recurrent and co hæmorrhages. As bearing upon this question of longe of patients suffering from thoracic aneurysm and their being disqualified for work which necessitated conside strain, I cannot do better than quote the case of Dr. Ge A. Gibson of Edinburgh alluded to by the late Sir Wil T. Gairdner in Allbutt's System of Medicine.[1] The pa was a man, aged 39 years, a lamp-lighter by occupation, lived for 12 years after his aneurysm was detected and during that period frequently "undertook the duties of keeper of one of the Edinburgh monuments which inv his ascending sometimes 50 times a day to a height of al 200 feet."

Although it is by the deposition of clot within the sac the further development of aneurysm is checked and physical signs of the tumour as well as the symptoms ca by it become altered in character there are, it need be mentioned, different kinds of clot to be considered in relationship. Cure can only take place through org[illegible] *of the clot. This occurred so completely in the* [illegible] whose case is the subject of these notes that although a aneurysm of the thoracic aorta was found after death it consolidated and its clot so thoroughly organised that it rise to no symptoms, it had apparently ceased to and in no way contributed to the fatal [illegible] On microscopical examination of sections of the ane the outer part of the clot is observed to have transformed into dense layers of fibrous tissue. Orga has completely taken place. Numerous large [illegible] shaped fibroblasts can be seen in the outer half thrombus. The altered layers of fibrin are observed becoming encroached upon by new capillaries and [illegible] tion tissue cells.

Newcastle upon-Tyne.

A CASE OF

PUTATION THROUGH THE HIP-JOINT N WHICH THE HÆMORRHAGE WAS CONTROLLED BY INTRAPERITONEAL COMPRESSION OF THE COMMON ILIAC ARTERY.

. W. ROUGHTON, M.D., B.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE ROYAL FREE HOSPITAL, GRAY'S INN ROAD, LONDON, W.C.

E patient, a girl, aged 13 years, was admitted to the l Free Hospital on Nov. 19th, 1908, having sustained a ared femur through falling from a tram-car. At the it was thought that the fracture was an ordinary one. matter of routine a skiagram was taken. It was then l that there was a very oblique fracture of the upper of the femur. Extending from the base of the great anter, about five inches down the shaft, the line of ure passed through an oval area, which was much less than the rest of the bone. On inquiring more ly into the nature of the accident it was found that girl had slipped from one step to the next one and suddenly sat down on the upper step. The amount iolence was clearly insufficient to break a normal r. It was obvious that we had to deal with a ntaneous" fracture passing through some kind of new th. It was therefore decided to cut down upon the ure and to investigate the lesion. Consent to perform mputation, should it be necessary, was obtained from arents.

Nov. 27th an incision was made from the great anter extending seven or eight inches down the outer of the thigh. The fracture was found to pass through panded portion of the femur dividing it into an anterior a posterior portion. The fractured part of the femur ollowed out into a cavity extending up into the base of great trochanter; it was apparently filled with it blood clot; on cleaning it out I removed a small of "growth" of the size of a date from the upper end ie cavity. This was subjected to rapid microscopic ination and was reported to be probably sarcomatous ot of the myeloid variety. I then decided to amputate e hip-joint. The common femoral artery and vein were through a separate incision opposite Poupart's ligament. st this was being done my colleague, Mr. T. P. Legg, ed the abdomen in the manner described below and made al pressure on the common iliac artery. The exploratory ion was then converted into a racquet-shaped incision cling the thigh at the junction of the upper and lle thirds. The skin flaps thus formed were re-ed for nearly half their length, and the muscles on anterior and outer aspect were severed as they into view; the head of the femur was disarticulated the posterior muscles were divided from within outwards. rteries spurted and the blood lost was apparently only which belonged to the limb below the site of amputa- There was a moderate degree of shock. This would ably have been less marked had not the assistant who been told off to do intravenous saline infusion experi-d great difficulty in finding a suitable vein. The patient e an excellent recovery.

e following report of the specimen removed and of its oscopic characters is kindly furnished by Miss Chambers, . Lond., clinical pathologist to the hospital:—

line of fracture, the fact that it is most marked where most movement has occurred—i e., at the lower end—that it is elsewhere comparatively slight, the lack of softening of the bone and taking into

cystic distension of the shaft.

The Control of Hæmorrhage in Severe Operations about the Hip.—In May, 1898, Mr. W. H. Battle (at that time one of my colleagues at the Royal Free Hospital) asked me to see a case of traumatic gluteal aneurysm. I suggested that the internal iliac artery should be compressed by the finger introduced through a small abdominal wound whilst the aneurysm was being dealt with. I did this whilst Mr. Battle operated and was able to control the bleeding most effectually. The case is published in the *British Medical Journal* of Nov. 5th, 1898. No further opportunity of trying this method occurred until last September, when I compressed the common iliac whilst my colleague Mr. Legg amputated at the hip-joint for sarcoma of the femur. The amount of blood lost was trivial.[1]

On referring to the literature of the subject I find that McBurney[2] was the first to describe the method. It has also been used by Raymond Johnson[3] in a case of aneurysm in the groin. With the exception of a scanty reference in Jacobson's "Operations," I find no mention of the method in the British text-books in common use. I therefore infer that the method is not so well known as it deserves to be.

The incision should be through the outer third of the sheath of the rectus, the muscle being displaced inwards; a clip may be placed on the deep epigastric artery to control any collateral circulation from the internal mammary. The incision through the posterior sheath and peritoneum should be just large enough to admit two fingers comfortably. The index and middle fingers are introduced and placed on the common iliac artery in such a way that the tip of the longer middle finger reaches just beyond the vessel, whilst the tip of the shorter index finger just reaches to the middle of it. In this manner the artery is safely pinned against the vertebral column and cannot slip away. The pressure of the fingers may be reinforced by the disengaged hand laid outside the abdominal wall. At the end of the operation the wound is sutured in the usual manner. By this method every vessel severed in amputation at the hip-joint can be absolutely and certainly controlled without in the least degree interfering with the freedom of the operator. In these respects I believe it is far superior to every other method. The only objections that can be urged against it are the slight additional risk of opening the peritoneum and the necessity for one more competent assistant.

Queen Anne-street, W.

THE USE OF INTRAPERITONEAL COMPRESSION OF THE COMMON ILIAC ARTERY DURING AMPUTATION THROUGH THE HIP-JOINT.

BY T. P. LEGG, M.B., M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE ROYAL FREE HOSPITAL, GRAY'S INN-ROAD, LONDON, W.C.

A YOUTH, aged 16 years, was admitted to the Royal Free Hospital on Sept. 21st, 1908, suffering from a large swelling in the lower part of the left thigh. Three months previously he had been struck by a piece of wood just above the knee-joint. At the time nothing abnormal was observed, but a month later a hard swelling was noticed on the anterior surface of the left thigh. It rapidly increased in size during the succeeding fortnight and he became unable to walk or to bend his knee. On examination a large tumour involving the e circumference of the left femur in its lower half was l. The tumour had the usual characteristics of a steal sarcoma and this diagnosis was confirmed by a ram. The limb below the knee was œdematous and a small range of movement was possible in the joint. e was no evidence of secondary deposits in the lungs, he inguinal lymphatic glands were enlarged.

---

[1] See report of Mr. Legg's case on this page.
[2] Annals of Surgery, 1894, vol ii, p. 181.
[3] Transactions of the Clinical Society of London, vol. xxxi, p. 283.

nputation through the hip-joint was performed on 30th. The femoral artery and vein were ligatured in places at Poupart's ligament and the vessels were ed between the ligatures. While this was being done, olleague, Mr. E. W. Roughton, opened the abdomen gh a short incision just inside the left linea semilunaris, luring the remainder of the operation compressed the non iliac artery. The amputation was done through the ior racquet incision, the handle of the racquet being ed in part by the vertical incision through which the al vessels had been exposed and ligatured. The flaps sted of skin and subcutaneous tissues, the muscles cut as short as possible. The amount of blood lost quite small and very little shock followed the operation. rtunately the wound became infected and a portion of ap sloughed; the abdominal incision healed by primary . From the pus in the stump a pure culture of rium coli commune was obtained. The patient left the tal on Nov. 23rd, only a small sinus remaining in the p.

examining the specimen the muscles were found to be nsively infiltrated by a soft white growth which on oscopic examination proved to be a spindle-celled ma. The glands did not contain any growth.

reason for publishing this case is to bring forward a od of controlling the hæmorrhage by compression of the non iliac artery through an abdominal incision during performance of an amputation through the hip-joint. method is both simple and efficacious, but it is not rently so well known as it deserves to be, and it was my ague, Mr. Roughton, who suggested its use to me. It is a new method, for an account of its employment in ar cases will be found in a paper by McBurney in the *ls of Surgery* for August, 1894. The ordinary texts on operative surgery do not contain any reference to nd in the last edition of Jacobson and Rowlands's erations of Surgery" it is referred to in a line and a half ll print. When amputation through the hip-joint is done [illegible] the muscles should be cut as [illegible] tachments; this is impossible [illegible] th's method, or a tourniquet [illegible] rhage. During the division ne muscles, large branches from the obturator, sciatic, gluteal arteries are severed, and by compressing the non iliac artery the hæmorrhage from these vessels can ompletely controlled, and as the loss of blood is one of most important causes of the shock which follows the ation, this important factor can be eliminated. More-, by relaxing the compression of the common iliac artery time to time whilst the divided vessels are being picked y the pressure forceps, it is easy to see the exact spots e to apply the forceps, thus rendering the applica- of the ligatures quite simple and reducing the unt of hæmorrhage during this part of the opera- to a minimum. If the common iliac artery is iently controlled, the common femoral need not be liga-d before it is divided; but as this vessel and the corre-ding vein have to be tied it is perhaps better to ligature n both at the commencement of the operation. It is aps needless to point out that the common femoral vein ld be tied or held by forceps before it is divided. To press the common iliac artery the abdomen should be ned just inside the linea semilunaris, and the rectus cle is displaced inwards. The incision need only be t three inches in length, and placed so that its centre st below the level of the umbilicus; the peritoneum is ded so as to permit the insertion of a couple of fingers. intestines are displaced to one side and the artery is for on the fifth lumbar vertebra, against which it is pressed by the palmar surfaces of the last phalanges of first and second fingers. No great amount of force is uired to completely arrest the circulation, and con-nently no ill effects will follow. If a competent assistant t hand he can open the abdomen whilst the surgeon is ng the common femoral vessels and close it whilst the flaps of the stump are being sutured. If such cannot be obtained the length of time of the whole operation will be slightly prolonged—viz., by so much time takes to open and close the abdomen. The amount of shoc is not appreciably increased by this procedure, and in thes days there should be no danger of peritonitis, so that th method deserves to be more widely employed.

It is interesting to notice that in the case here recorded although the amputation wound became infected, the abdominal incision healed by primary union.

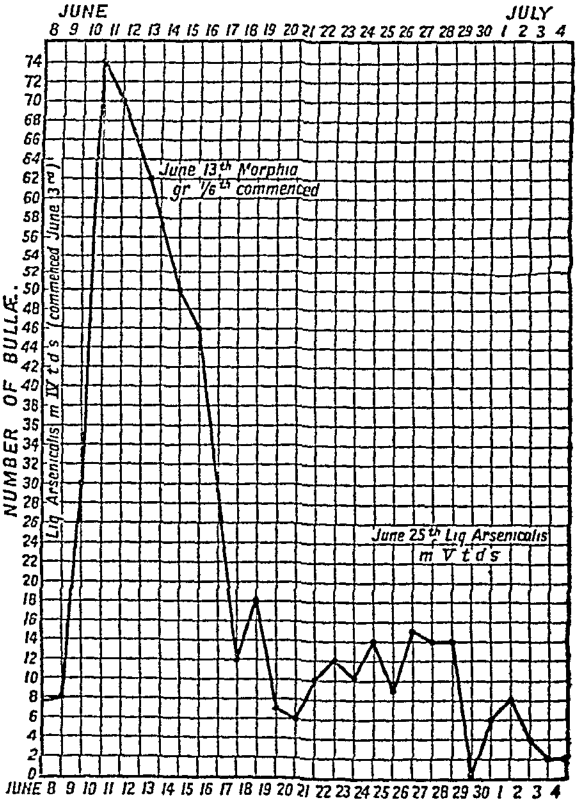
Harley-street, W.

NOTES ON A CASE OF PEMPHIGUS IN NONAGENARIAN; RECOVERY.

BY THE LATE JAMES GREY GLOVER, M.D. EDIN.

[THE following case appears worthy of record on accoun of the great age of the patient and of the remarkable effec produced by the exhibition of morphine after the apparen failure of arsenic. We are indebted to Dr. Alison Glover fo sending us his father's manuscript.]

The patient, aged 90 years, had had a very strenuous an healthy life. During the last five or six years he had ha occasional severe attacks of epistaxis necessitating pluggin of the nostrils and he had "aged" rather rapidly. Som 18 months before I saw him eczematous patches appeare on the left arm and left leg, and in October, 1907 bullæ were first observed. For nearly six months the bleb were confined to the exterior aspect of the left forearm an to the outer side of the left thigh and appeared only once or twice a week. *The patient was otherwise well, the pulse* being regular and remarkably constant at 72 per minute. Since the skin trouble commenced there had been no epistaxis. The urine throughout had been free from sugar and albumin and contained a good percentage—2·3—of urea. In May, 1908, the bullæ on the right arm became more frequent and the patient was given gradually increasing doses of arsenic—one minim of Fowler's solution on May 7th, two minims on the 28th, and three minims on the 30th—three *times a day.* On June 1st the itching became very severe and the patient had no sleep. On the 3rd the arsenic was increased to four



The vertical figures show the number of bullæ upon the dates which are indicated above and below.

minims three times a day, with some improvement. On the 8th there were 13 new bullæ, the scrotum and thighs being the worst parts. On the 9th 30 fresh bullæ were counted and the itching during the night was terrible. On the 10th 74 fresh bullæ appeared, chiefly on the arms, the axillæ, the thighs, the scrotum, and the legs. They were almost confluent. On the 11th 70 new bullæ appeared. On the 12th the patient had a restless night in spite of the administration of [illegible] there is no record of [illegible] next two days, it being almost impossible to count. On the 13th, after having no sleep all night, the patient was ordered one-sixth of a grain of morphine. On the 14th the patient, having had an excellent night, the new bullæ numbered 50, and were flaccid rather than tense, usually a bad sign. On the 15th, after a bad night, they numbered 47, and another one-sixth of a grain of morphine was ordered. On the 16th the new bullæ were "much fewer." On the 17th they numbered 11, on the 18th 16, and on the 19th eight, one-sixth of a grain of morphine being given by the mouth each night. On the 25th the dose of Fowler's solution was increased to five minims three times a day, the irritation being still very great. For the next three weeks bullæ appeared on an average of three or four a day, gradually diminishing until on July 15th the patient had four consecutive nights without any fresh bullæ, then a few nights with single bullæ, and then an almost complete cessation. With very short intervals the arsenic was continued. There was great dryness of the skin and some exfoliation, but otherwise the skin recovered wonderfully. The condition of the patient, however, remained at a much lower level than before the illness, which has naturally "aged" him a great deal.

The case well bears out Hutchinson's dictum that it is precisely in senile subjects that exceptional features occur, and that arsenic is every now and then found to fail. The prognosis in aged subjects is always grave, and I can find no recorded case in which the age exceeded 71 years, which makes a recovery at the age of 90 years very remarkable. Other points of interest in the case are the previous history of epistaxis and the complete failure of all local measures to arrest the disease or to allay the frightful irritation.

JUXTA-EPIPHYSEAL INFLAMMATION OF THE UPPER END OF THE HUMERUS.

BY ARTHUR F. MESSITER, M.R.C.S. ENG., L.R.C.P. LOND.

A DAY or two after a fall from a chair, a boy, two and a half years old, was found to be feverish and suffering from a painful and swollen shoulder. When I saw him 12 days after the commencement of his illness he was evidently in a very critical condition, and on opening a large abscess under the deltoid I found that the shaft of the humerus was separated from the upper epiphysis and divested of periosteum for an inch or more; the bare surface of the epiphysis was smooth and cartilaginous. Some months afterwards a piece of bone of the size of a finger-nail was extruded and the opening then quite healed up. An interesting feature is that there is absolutely no shortening due to arrest of growth, and the arm is practically as good as the other. A skiagram taken five years afterwards shows the shaft and epiphysis reunited, the space occupied by the conjugal cartilage being clearly seen. *The growth of the* shaft since its separation is shown by a bend in it, evidently caused by a slightly faulty "setting" of the shaft with the epiphysis owing to the tilting of the latter by the spinati muscles. This angular union is commemorated by the bend being maintained in the shaft as it grew from the epiphyseal cartilage. The bend has receded from the cartilage three inches in five years. This case is a good illustration of the fact that in juxta-epiphyseal ostitis the inflammatory products do not gain access to the shoulder-joint, owing to the attachment of the periosteum to the conjugal cartilage, a fact which, I presume, is recognised at the present time, but was certainly not generally taught a few years ago, for in the 1897 edition of a well-known standard text-book I find the statement that "as the inner part of the epiphyseal cartilage is just within the capsule the pus in suppurative epiphysitis will find its way into the joint."

Mr. Charles White of Manchester in 1769 read a paper before the Royal Society, entitled "An Account of a Case in which the Upper Head of the Os Humeri was Sawn Off, a Large Portion of the Bone afterwards Exfoliated and yet the Intire Motion of the Limb was Preserved." This case is well known to all students of surgical history and has up to the present time, so far as I am aware, been admitted to be a sound basis for the claim of Charles White to be the pioneer in the matter of excision of diseased joints. This paper, illustrated by a plate, was subsequently printed in his "Cases in Surgery," a copy of which is in my possession. "Edmund Pollitt, aged 14, was admitted into the Manchester Infirmary, April 6th, 1768. He had been suddenly seized, about a fortnight before, with a violent inflammation in his left shoulder, which terminated in a large abscess which was opened with a lancet a few days before his admission. The orifice was situated near the axilla, upon the lower edge of the pectoralis major, and through it I could distinctly feel the head of the os humeri totally divested of its bursal ligament. The matter which was very offensive and in great quantity had made its way down to the middle of the humerus and had likewise burst out at another orifice just below the processus acromion, through which the head of the os humeri might easily be seen. The whole arm and hand were swelled to twice their natural size and were entirely useless to him. He suffered much pain, and the absorption of matter had brought on hectic symptoms, such as night sweats, diarrhœa, quick pulse, and loss of appetite which had extremely emaciated him. ...... On the fourteenth of the same month I began my incision at that orifice which was situated just below the processus acromion and carried it down to the middle of the humerus, by which all the subjacent bone was brought into view. I then took hold of the patient's elbow and easily forced the upper head of the humerus out *of its socket* and *brought it so entirely* out of the wound that I readily grasped the whole head in my left hand and held it there till I had sawn it off. ...... In about five or six weeks I perceived the part from which the bone had been taken had acquired a considerable degree of firmness, and he was able to lift a pretty large weight in his hand. At the end of two months I found that a large piece of the whole substance of the bone that had been denuded by the matter was now ready to separate from the sound and with a pair of forceps I easily removed it. After this exfoliation the wound healed very fast, and on August 15th he was discharged perfectly cured. On comparing this arm with the other it is not quite an inch shorter; he has the perfect use of it and can not only elevate his arm to any height but can likewise perform the rotatory movements as well as ever. The figure of the arm is in no ways altered and from the use he has of it and its appearance to the eye and touch I think I may safely say the head, neck, and part of the body of the os humeri are actually regenerated ...... the osseous matter could not proceed from the scapula, the glenoid cavity of that bone not being divested of its cartilage."

I submit that this was not a case of excision of the head of the humerus but the removal of the upper part of the shaft, that the head of the bor [illegible] cavity, and that the cartilag [illegible] epiphysis tilted upwards and [illegible] glenoid cavity. Indeed, Fig. [illegible] is obviously not the head of the humerus but the upper *carious end of the shaft*, and his necessarily implied suggestion that the whole of the epiphysis became carious and [illegible] in three weeks [illegible] glenoid cavity [illegible] Poland, in his [illegible]tes cases which show that it is the rule for the joint not to be opened in separation of this epiphysis unless unusual violence has been applied, and he mentions one case (p. 182) which is so apposite to my present argument that I reproduce his quotation: "M. Guéretin *has reported an instance* in which the wound was caused by the lower fragment piercing through the deltoid and integuments. The purulent discharge from this wound was enormous. Amputation was performed on the forty-ninth day and death ensued on the sixty-third. It is remarkable that the amputation was intended to be and was supposed to have been done through the joint, but at the autopsy the head of the bone was found in place; its end was hollowed out to the depth of about one-third of an inch, and this concave surface had been mistaken for the glenoid cavity."

Epworth.

GRADUATED REST IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY EDWARD E. PREST, M.A., M.D. CANTAB.,
MEDICAL SUPERINTENDENT OF THE AYRSHIRE SANATORIUM.

I AM well aware that in choosing the above title I lay myself open to a charge of pedantry, nevertheless the title was chosen after very careful consideration in order to make conspicuous the paramount importance of rest in the treatment of pulmonary tuberculosis. Graduated rest may be the same thing as graduated exercise or graduated labour, and yet there is a difference in the emphasis. In the one case the rest and in the other the exercise is hidden in the common term "graduated," but the rest factor has been in the past, I think, far too much obscured.

It is well to remember before going on to a consideration of this subject that a considerable number (though doubtless a small percentage of the whole) of persons suffering from developed tuberculosis of the lungs make a good recovery without any treatment worth mentioning. These cases must be remembered before ascribing cures to any given method of treatment, and in the consideration of treatment the cases should not be carefully selected.

It may be as well to observe at the outset that even in the most slackly conducted sanatoriums a certain measure of rest has always been enforced, and this, which was probably the determining factor in any good results which were obtained, has too often been placed in the background, and methods of treatment the only distinction of which is their extremeness have often received the credit.

It will be well before proceeding further to consider how persons suffering from consumption were treated before sanatoriums with their much improved, though often faulty, methods were introduced. In order to illustrate what I mean I cannot do better than quote a portion of a lecture delivered by Professor Niemeyer of Tubingen[1] at least so [illegible] ago as 1866. He makes the following observations in [illegible] of other remarks on treatment:—

> [illegible] first case strict measures are as a rule considered useless and [illegible]forcement unnecessary. The patient is allowed to follow his [illegible] until the rising pyrexia and the increasing debility force [illegible] to remain at home, or until hæmoptysis, pleuritic pains, the appearance of dulness over the chest urgently demand that the supposed "secondary" pneumonia and pleuritic processes be submitted at least to a symptomatic treatment. It will not be said that I exaggerate, let us be sincere! Is not this "*laisser aller*" practice founded on reasoning of everyday occurrence with regard to the affection under discussion? It is seldom that a medical man reproaches himself for having by his carelessness been guilty of the developments of a phthisis florida (galloping consumption). ...... It is true, even in case the physician should have fully recognised the nature of the disease, he will not be able to cut it short at once, but still he has every reason to give the strictest orders, he must do everything in his power to protect the patient from injurious influences; and to place him under such conditions as may be expected to put a stop to the further ext[illegible] termination in cheesy [illegible]
> ...... Let anyone mak[illegible]

Anyone who will take the trouble to enforce this method of treatment will speedily be convinced of the soundness of the above observations.

There is no doubt that improvements in the methods of diagnosis have provided cases for treatment which a few years ago would not have been regarded seriously; some of these, doubtless, never got worse. Those chiefly referred to here are distinguished by the occurrence of an initial hæmoptysis, or an initial pleurisy: two conditions fortunately recognisable without much difficulty. A few years ago pleurisy was not treated differently from acute pneumonia or influenza, its possible or probable ultimate development was not realised, and persons suffering from even a considerable hæmorrhage were not treated for any length of time; carelessness was no doubt partly attributable to the num of cases which never relapsed.

The following tables show the manner of incidenc tuberculosis occurring in 225 men and 73 women, collec by me from the records of the Hospital for Consumption Diseases of the Chest, Brompton. The duration of t between the occurrence of the initial symptoms and th admission to hospital is given in order to indicate the aver relative acuteness of the process.

TABLE I.—*Showing the Manner of Incidence of Tubercul occurring in 225 Men.*

Symptoms.	Cases.	Percentage.	Average duration before admission.	Extremes duration before admissio
Cough	77	34·2	21 months	—
Hæmoptysis	42	18·6	34 "	Longest years. Shortest th months.
Pleurisy	41	18·2	52 "	Longest years. Shortest th months.
Miscellaneous, including loss of flesh, weakness, dyspepsia, and dyspnœa	31	13·7	15 "	—
Influenza and catarrh associated with fever	18	8·0	15 "	—
Laryngeal...	8	3·5	16 "	—
Commencing like an acute pneumonia ...	8	3·5	22 "	—

TABLE II.—*Showing the Manner of Incidence of Tubercul occurring in 73 Women.*

Symptoms.	Cases.	Percentage.	Average duration before admission.	Extremes duration before admission
Cough	24	32·8	26 months	—
Hæmoptysis	15	20·0	33·7 "	Longest years. Shortest months.
Pleurisy	19	26·0	47·8 "	Longest years. Shortest months.
Miscellaneous, including loss of flesh, weakness, dyspepsia, and dyspnœa	4	5·5	22 "	—
Influenza and catarrh associated with fever	3	4·1	8 "	—
Commencing like an acute pneumonia ...	2	2·7	8·5 "	—
Associated with pregnancy	6	8·2	15·4 "	—

It may be noted from a consideration of these tables th all the cases, with the exception of those commencing wi hæmoptysis or pleurisy, must have run a fairly rapid cour

The chief measures at present adopted for the treatment tuberculosis may be stated generally to be—(1) rest; (2) suitable and sufficient dietary; (3) graduated exercise; a (4) fresh air. The chief controversies have arisen over t relative proportion of rest to exercise which is necessary bring about a cure; my intention is to deal chiefly with th aspect of treatment.

It will be well to mention here certain particulars wi regard to the theory of the formation of opsonins. It supposed that for the satisfactory evolution of opsonin occur the following factors must coöperate: certain of t products, at present but imperfectly defined, of the speci micro-organism, in this instance the tubercle bacillus, mu be able to find their way into the fluid tissues of the body for convenience we will call these products tuberculin. T formation of toxins and antitoxins, though undoubted intimately interwoven with the subject, will only be indirectly referred to here, the antibacterial products being chiefly considered. In addition to the presence of tuberculin there is some reason for supposing that movement of muscle[2] is necessary for the production of opsonin; this substance is probably largely instrumental through raising the blood pressure. It might be inferred from the above that exercise would prove more beneficial than rest in the treatment of *tuberculosis, nevertheless it is probable that much more harm* is done by excessive exercise than by excessive rest; the reason for this will, I think, appear later.

---

[1] Clinical Lectures on Pulmonary Consumption, by Felix von Niemeyer, M.D., The New Sydenham Society, 1870.

There is reason for supposing that active movements and mechanical disturbance of the actual focus of disease will produce an increase in the amount of the products of the bacillus and will assist in the distribution of these products. This process corresponds clinically with an increase of local signs of inflammation, following upon movement and mechanical disturbance of the parts. Massage of joints when beneficial is probably so on this account.

It must be remembered that rest is undoubtedly the most potent therapeutic factor we possess for arresting the spread of tuberculosis; it is the only way of preventing the laying down of fresh tubercles, and as consolidation largely consists in a great agglomeration of tubercles *rest* may often prevent the occurrence of considerable consolidation, and as consolidation is antecedent to excavation, and with excavation in order to protect the healthy lung, we require a *considerable amount of fibrosis, by keeping* a patient in bed we may prevent the formation of a chronic invalid. The great difficulty in treating any tubercle which has been allowed to form lies in the very nature of its anatomical structure, for if tubercle bacilli lie long enough undisturbed in the tissues they become surrounded by avascular tissue composed of cells of various kinds which for lack of nourishment degenerates into caseous masses. Tubercles which have become avascular represent portions of lung tissue which have passed beyond the possibility of recovery, though perhaps not of some kind of repair, and no treatment can possibly bring about a return to the normal condition. The portion of lung lost is lost as irrevocably as an amputated limb. These caseous masses may become shut off by fibrous tissue from the healthy lung tissue, or the fibrous tissue may only imperfectly surround them, the disease spreading at one or other edge, or the mass may protrude into an air vesicle or bronchus and be expectorated, leaving a cavity which may vary in size from a millet seed to one occupying the whole of one lobe. The former may be comparatively unimportant, the latter is very serious, and all degrees between these two extremes are to be met with. The number of tubercles, therefore, which are allowed to become bloodless has a very important bearing upon treatment, for when caseous masses have been formed or cavities have been excavated with walls consisting of fibrous tissue they become beyond the reach of any known treatment and, it is quite safe to prophesy, beyond the reach of any treatment which will ever be discovered, and no antitoxin or tuberculin or serum can ever cure these areas. Avascular tubercles, though producing no tuberculin that can be curative, always remain sources of danger owing to the virulent tubercle bacilli which they contain.

When an early acute case is put to bed the conditions existing in the lungs may be illustrated, perhaps somewhat

about a cure. It is here contended that rest of an absolute kind will prevent these last-mentioned tubercles from becoming bloodless; they will, of course, never be visible anatomically.

For the purposes of argument tuberculous lesions have been divided into the following classes: 1. Tuberculosis affecting the skin and mucous membrane. 2. Tuberculosis of joints. 3. Tuberculosis of solid organs. 4. Tuberculosis of the lungs: (*a*) acute febrile tuberculosis (see definition further on); (*b*) tuberculosis affecting chiefly the pleura; (*c*) localised tuberculosis of one apex, diagnosed by the occurrence of hæmorrhage; and (*d*) chronic tuberculosis, chiefly characterised by excess of fibrosis—(1) when the infection is pure, and (2) when the infection is mixed. 5. Tuberculosis of the larynx.

Before continuing further it will be well to recapitulate the conditions necessary for a cure to be brought about. The right kind and right amount of tuberculin must be present; the right kind is always potentially present and may be derived from the patient's own lesions. Furthermore, the tuberculin must be able to reach the general tissues of the patient; in addition, it is assumed a substance derived from muscle must be present.

Tuberculosis affecting the skin is extremely chronic, yet it is very persistent and spontaneous healing seldom occurs; it is difficult to demonstrate the tubercle bacilli in the lesions, owing to their scanty number; probably very little tuberculin is formed. We also noticed that the skin is comparatively speaking motionless, or at least seldom changes its position relatively to the rest of the body, and hence the lesions are not by movement provoked into activity; these patients are, however, able to take plenty of exercise; further, the diseased part is kept at rest, which as a rule tends to promote healing. We might therefore conclude that lupus failed to heal owing to the absence of sufficient tuberculin. There is some evidence that this is the case, for we find that treatment by the Finsen light, hot sand bags and the x rays, all of which cause some determination of blood to the affected part, will in a considerable proportion of *cases effect a cure; efforts are here made to* provoke the lesions to greater activity; in addition, a certain number of cases have been cured by the injection of tuberculin.[3] It has also been proved that in some cases where persons suffering from lupus have developed active disease in the lungs the lupus has cleared up completely before death.[4]

We will now pass on to consider tuberculosis affecting joints It has long been taught that the best method of treating tuberculous joints was by immobilisation on a splint. We may now inquire how the necessary conditions for cure are fulfilled in the case of joints. The disease may be fairly acute or very chronic; in the former event too much and in the latter too little tuberculin will be produced. To overcome the former trouble we may try immobilisation and to remedy the latter fault we may employ active movement, passive movement, or massage. Although it may be necessary to place the affected limb on a splint this will not prevent the patient from taking exercise with his other limbs; the necessary muscular components will therefore be produced. Tuberculosis of joints is, as a rule, nothing like so chronic as tuberculosis of the skin, we should, therefore, expect this kind of tuberculosis to be fairly amenable to treatment, and this is found to be the case in practice.

Before passing on to consider tuberculosis of the lungs it becomes necessary to define what is meant by an acute case; many of the cases which come under the present definition would not be regarded as acute by the majority of practitioners. By acute is meant any case which does not exhibit a perfectly normal *temperature In order to discover accurately* the temperature it is absolutely necessary that the patient should be put to bed and the temperature taken in the rectum at 8 A.M., 12 noon, 6 P.M., and 8 P.M., no temperature is regarded as normal which does not fall at least as low as 97·9° F. (36·6° C.), better 97·8° F., in the morning and which does not rise above 99° F. (37 3° C.) all day when the patient is kept absolutely at rest, including silence. It is assumed, for the purpose of argument, that if the temperature rises higher than this auto-inoculation is too considerable or too frequent, or both.

In tuberculosis of the lungs the amount of tuberculin may be too large—this is what occurs in acute cases. How, then, can we limit the amount of auto-inoculation? It has been found from clinical experience that the only sure way of limiting the amount of auto-inoculation is by limiting the movement of the foci of disease in the lung; this can only be accomplished by resting the lung as a whole; furthermore, the lungs, like the heart, can only be approximately rested, and then only by reducing the movements of the body to a minimum; in order, *therefore, to* prevent mechanical disturbance of the diseased part we must rest the patient absolutely in bed; in addition, as talking causes considerable acceleration of respiration, we must keep the patient silent, and coughing must be reduced to a minimum, if necessary, by the administration of opium or one of its efficient derivatives. It will be observed that although excessive auto-inoculation be checked these patients are deprived of the substance derived from the movement of muscle. We may, therefore, expect to meet with difficulties in treating these cases, and the absence of the factor may account for the long periods it is sometimes found necessary to keep these patients recumbent. If the substance referred to has anything to do with raising the blood pressure the administration of adrenalin, or beef-tea, or raw meat might be expected to be beneficial. Massage of the limbs I have thought to be useful in some cases.

[4] Tuberculosis in Infancy and Childhood, edited by Kelynack. Baillière, Tindall, and Cox. P 158.

The difference, therefore, in behaviour of the different varieties of tubercle depends largely on a question of movement; the lungs and the heart being the only organs which cannot be rested absolutely can only be rested approximately by cessation of all movements. In tuberculosis of the pleura a new factor comes into play, the limitation of movement present in all pleurisies and very persistent in its action. Here a natural splint is provided which may be the chief reason why tuberculosis of the pleura usually runs such a benign course; auto-inoculation because of this is reduced in amount, and the diseased part is kept fairly still, muscular exercise not producing such disastrous results. When effusion takes place the rest of the part is more complete and a cure occurs fairly frequently after a moderate effusion.

In cases where hæmoptysis is the first sign it will usually be found that a vessel has given way in the middle of a comparatively small focus of disease at one or other apex. There is usually a considerable amount of fibrous tissue round the lesions, making delimitation by the x rays easy. These people are often in fair health at the time of the hæmorrhage. It is probable that in many of these cases but for the hæmorrhage the disease would have gone on to complete healing. Most of the obsolescent tubercle found when patients have died from other affections probably represents potential hæmoptyses, which fortunately never occurred. The slight constitutional symptoms from which these patients suffer lead us to infer that very little tuberculin is formed in the lesion, and what is formed finds great difficulty in reaching the general system owing to the fibrosis; in addition a small focus surrounded by dense fibrous tissue will undergo very little mechanical displacement even during active respiration, and therefore the disease is not likely to be provoked into activity by exertion, unless very severe or during excessive movements of the arms, as in digging. The substance derived from muscular action will, as a rule, not be wanting. The resemblance between these lesions and lupoid ulceration of the skin will occur to everyone. The behaviour of many of these cases is similar to lupus, with the difference that the lungs are a much more vascular organ than the skin. The disease often progresses slowly, the lung being gradually eaten away; it may take years for any considerable destruction of lung to take place. The hæmorrhages are often recurrent, in the intervals the patient enjoys excellent health. This class of case may prove difficult to cure, but is, as a rule, easy to benefit, and in any event their course is often prolonged; this may be gathered from a study of Tables I. and II.

The next class includes cases of chronic tuberculosis in which treatment has failed—as a rule because sufficient rest has not been prescribed sufficiently early and for sufficiently long periods. There is reason for supposing that chronic cases are largely due to exercising too freely, what have here been defined as acute cases. The chief feature in chronic tuberculosis is the presence of a large amount of fibrosis, which is itself largely determined by antecedent bloodless tubercles. This fibrous tissue cuts off the more or less extensive caseous masses, or when these have been exfoliated the more or less extensive cavities, from what healthy lung tissue remains. We find consequently that these patients are subnormal generally, short of breath, either from destruction of lung tissue or oftener perhaps due to the reduction of the total lumen of the blood channels through the lungs, showing itself as a failing heart. Owing to fibrosis any products of the lesions find difficulty in reaching the general system and constitutional symptoms are largely absent. The tubercle bacilli hidden in the thick walls of cavities are very persistent, being shielded by the fibrous tissue from harm. Owing to the shutting off of a free channel for the tuberculin from the lesions by fibrous tissue they show little sign of spontaneous healing; the disease as a rule tends to creep slowly on, the progress often marked, however, by exacerbations due to infective sputum being sucked down bronchi leading to healthy lung tissue. In time, as a rule, other micro-organisms are grafted on the tuberculous lesions, and they fall into the class of mixed infections.

Before considering the next type it will be well to say something relative to the production of fibrous tissue in consumption. It will be admitted that when fibrous tissue is produced in excessive quantity much crippling takes place, and when its production is progressive it ultimately leads to the death of the patient by destroying the channels of the lesser circulation through the lungs. It has always been taught that fibrous tissue brings about a cure in consumption, and this is no doubt so far true that after the exfoliation of diseased foci their places, as in all other destructive lesions, must be taken by newly formed fibrous tissue; but it is unnecessary for the process to go beyond this stage; it is contended here that if acute cases—and practically all cases are acute to commence with—are exercised too early considerable areas of caseous tubercle are liable to be shut off permanently from the general system and are thus prevented from exfoliation, and if exfoliated, through their magnitude to leave behind them large cavities; with all the deplorable conditions usually associated with such formations a satisfactory cure when this state of affairs has been reached cannot be expected. In those instances where small lupoid patches occur it is true they may be shut off by dense fibrous tissue without much harm being done, and this is probably the *raison d'être* of the cures brought about by large amounts of physical exertion.

Laryngeal tuberculosis has been classified separately because it exhibits in such a remarkable manner the benefits to be derived from rest.

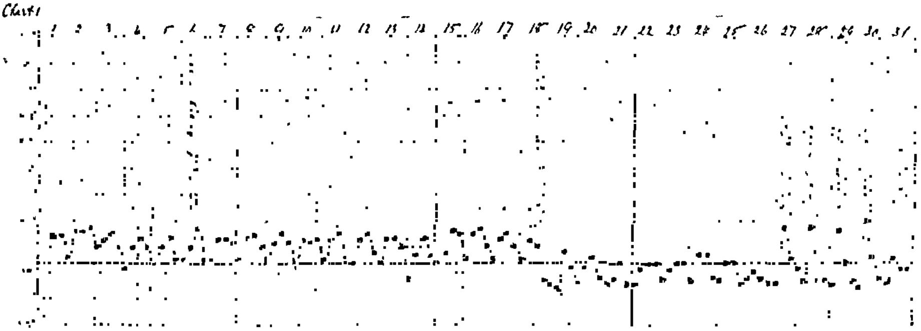
From the above considerations some guidance in the treatment of all cases of tuberculosis may, I think, be obtained. In the first place it must be insisted on that all patients who exhibit even the smallest sign of invasion by the tubercle bacillus must be treated with the utmost rigidity. When people have become seriously ill so much valuable time and valuable lung tissue have been irrevocably lost. The careful taking of the rectal temperature whilst the patient is kept in bed is the most reliable guide. If a patient is allowed to get worse and has never been rested in bed the medical adviser will find great difficulty in justifying his position.

So long as there is any fever as defined above, these patients must be kept at rest; the rest should always be in bed and each patient must have if possible a separate room. A sufficiency of fresh air can always be obtained in the rooms of an ordinary sanatorium. In my opinion nothing but harm can be done by putting these patients out on verandahs or by letting them lie about in long chairs; rest in bed is essential. Absolute rest in bed should be insisted on when, during rest in bed including silence, the temperature rises above 100·4° F. (38° C.) during any part of the day. As a rule it will be found that if these principles are enforced rigidly the actual period of solitary confinement will be very much reduced. When the temperature does not rise higher than 100·4° F. (38° C.) during the day I usually allow these patients to visit the lavatory and perform their toilets generally, in the hope that the substance derived from muscle may be produced in this way; otherwise they are kept in bed until their temperature sinks as low as 97·8° F. (36·5° C.) the first thing in the morning. It is extremely important that the temperature should be low before breakfast, and this should always be taken in the rectum, any other way being quite unreliable. The following case illustrates well the method pursued and also illustrates the danger these patients are in if walking about.

I visited Miss X about three weeks before she was admitted to a sanatorium. She had been ill for about four months, the trouble commencing with a cough and night sweats; she had, however, done her work until about a month before I saw her. She had at that time come to be medically examined and her doctor on first seeing her remarked on her healthy appearance. He found, however, on examining her chest considerable signs of disease at one apex and at once advised her to go to a sanatorium. This she decided to do, though opposed in the first place by her friends. When I visited her she was supposed not to be feverish and was pottering about all day, and in addition was playing the piano and singing solos. These latter amusements she gave up at my request, though she informed me that she was not *feeling ill.* She was well nourished, but signs of considerable activity were discoverable at one apex and her sputum was loaded with tubercle bacilli. The subjoined chart gives a very fair account of her progress during her first month at the sanatorium. It will be observed that according to the standard here set up she was feverish when first admitted and the fever continued for 18 days, and it is remarkable, though perhaps a coincidence, the way in which her fever fell after the first massage. Raw meat alone, as seen from the chart, had apparently no effect by itself. It may be well to state here that until her temperature fell to normal she was kept strictly isolated and discouraged from coughing. She lost her tubercle bacilli in three months.

Tuberculosis when attacking the pleura usually runs a much more benign course than elsewhere, a cure often taking place by means of such measures as are appropriate for acute pneumonia. We should therefore be cautious in ascribing a cure in these cases to any form of treatment which may be adopted. These patients should, like the former class, be kept in bed until all fever has subsided and then exercised very gradually. When these patients are rested completely, it will generally be found, as also in acute cases, that the breath sounds remain feeble for a considerable length of time, indeed, as a rule, until exercise is taken; they usually return more speedily after exercise has commenced. This, however, is not a reason for getting them up quickly, but rather the reverse, for feeble breath sounds are a sign that the lungs are at rest, and rest is the most powerful factor in the promotion of healing.

FIG. 1.



Temperature chart during the first month in the sanatorium.

I visited William Y——, aged 18 years, three weeks before he was admitted. He had been unable to work for three months. The illness had commenced with cough and sickness and he had night sweats for a fortnight, during which time he remained in bed. Since then he had been walking as much as seven miles a day and taking rides in tradesmen's carts and was not supposed to be feverish. Tubercle bacilli in clumps were present in his sputum. There were considerable signs of activity in at least two lobes. Both vocal cords were slightly affected. He was feverish, like the last patient on admission. He was accordingly put to bed and secluded and was given raw meat and massaged. His temperature did not become normal until 23 days after admission; on the nineteenth day it was found necessary to restrict his reading as this was keeping up his temperature. He lost his tubercle bacilli three months after admission. Space will not allow his chart being given.

I may say that both these patients were exercised with extreme care when first allowed up.

A case recently came under my care of a young man who had been confined to bed for three months without any fall in temperature; he was also steadily losing weight; I placed him on rigid silence and secluded him and his temperature fell to normal in ten days. I have at present a patient who had been kept in bed for about three months, with the result that his temperature had fallen from 102° F. (39° C.) to about 100·4° F. (38° C.), and there it stayed for some weeks; he was then kept absolutely silent and in 24 hours his temperature had fallen a degree Fahrenheit; from that point he continued steadily to improve and is now walking as much as eight miles a days without harm.

It is in my opinion extremely important that the temperature should fall at least as low as 97·8° F. (36·5° C.) in the morning before breakfast before the patient is allowed to get up. It is true that in a good many cases the temperature will fall ultimately, even supposing the patient be allowed to walk about, but it does not follow that he will be in as favourable a condition for cure as when it falls during rest in bed: in the former case it is probable that more bloodless tubercle, which necessarily means more destruction of lung, will have been laid down.

Cases commencing with an initial hæmoptysis are, as a class, the cases which exhibit the least fever and consequently require the least rest. Judging from the tables at the beginning of this paper they represent about 20 per cent. of the total number of cases. It will be found, however, that only a very small proportion of phthisical patients can dispense with rest in the first instance, for of those starting with hæmorrhage some will be found to be febrile; in my opinion, most, and all require some rest in bed at the commencement of the bleeding. The fever in this class of case as a rule subsides fairly rapidly. A parallel has already been drawn between these cases and lupus of the skin; now the main characteristic of lupus is its extreme chronicity, due to a comparatively non-virulent infection. These cases are generally comparatively non-febrile, and in order to promote a cure it seems advisable that some form of fairly violent exercise should be prescribed in order that either the indolent tubercle may be provoked into activity and so bring about a cure, or that the formation of considerable fibrous tissue around the comparatively small lesion may be facilitated; this can most readily be done by making the patient dig, as the movements of the arms are more likely to cause some disturbance of the focus in the lung than mere walking. Obviously this is an experiment fraught with some risk and these patients require very careful supervision; it has been carried out with success on a large scale by Dr. M. S. Paterson at Frimley.[5] It may be noted that the temperature in many cases of initial hæmoptysis shows no sign of going higher than 99·6° F., even after a long spell of hard work. These temperatures should, however, always be taken in the rectum immediately after the work and should not be allowed to rise higher than 100·4° F. (38° C.), which should sink with half an hour's complete rest to nearly 98·6° F. (37° C.). How unreliable taking the temperature in the mouth may be can be inferred from the accompanying chart where the temperatures after exercise were taken simultaneously in the mouth and in the rectum.

It should be remembered that the temperature of normal persons rises considerably after exercise, the amount varying with the severity of the exercise and the heat of the day. The great thing to do in treating chronic cases is to prevent their occurrence; these cases are at present only too numerous, and I fancy colour the ideas of many medical men when considering consumption. Unfortunately, some of these cases are always with us, though not all for long. Chronic cases, it should be remembered, probably are the most potent cause in the handing on of the disease, as tubercle bacilli shut away from healthy lung tissue, in the walls of cavities, by means of abundant fibrous tissue persist indefinitely and when expectorated are liable to infect the healthy. It is urged here that the formation of chronics can largely be avoided by the early, and sometimes prolonged, resting of cases of consumption. It will often be observed that patients who at first exhibit the most violent constitutional symptoms if they eventually survive ultimately make the most perfect recoveries; this is probably due to the severity of their symptoms, making it absolutely necessary that they should be confined to bed. It may, of course, happen that if the tubercles in an early case are more widely scattered, with considerable areas of intervening healthy tissue, more constitutional symptoms may be produced than if the same number of tubercles were packed close together, and that in the former case from anatomical considerations it will be easier for the lungs to deal with the trouble; whilst in the latter, owing to the massing of the tubercles, the way is paved for the production of chronic disease. When the patches of disease are not too large these patients may ultimately make good recoveries and are to be classed with cases commencing with hæmoptysis. Should there occur any exacerbation of the disease, these patients must be treated like the acute cases before mentioned.

---

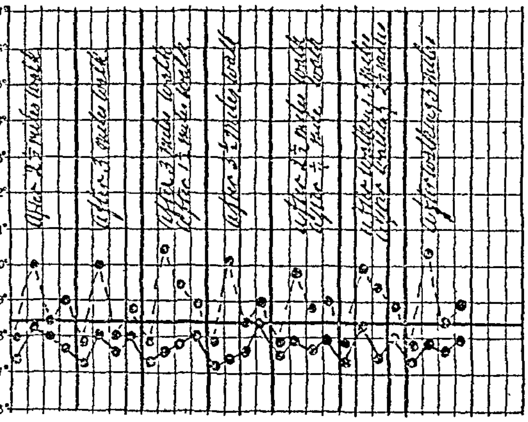
FIG. 2.



Interrupted lines = rectal temperature. Continuous lines = mouth temperature.

The treatment of tuberculosis of the larynx depends largely upon resting the vocal cords by insisting upon silence, and every effort must be made to diminish the cough, if necessary by means of large doses of opium or its efficient derivatives. This silence may have to be enforced for months. The opium here acts as a splint to the larynx. It may be here observed that coughing is one of the most harmful practices that a consumptive can indulge in, and when constant must always be checked. These patients ought never to be informed they are taking opium. Too frequent examinations of the throat should be avoided and acute cases should be examined very sparingly and never be asked to cough. Coughing may easily cause dissemination of the tubercle and can answer no useful purpose, as it is preferable to leave the differentiation of any crepitations that may be present to a more safe and convenient season. So soon as the temperature falls laryngeal patients may be allowed to take exercise.

If the above suggestions are carried out it will in almost all cases mean that the consumptive patient must first of all be rested, and it should be remembered that rest means something far more than is ordinarily understood by that term: it means as complete an approximation to absolute stillness obtainable, and for this reason, that whereas in ordinary injuries to limbs and the like, it is possible to keep the part at absolute rest by means of suitable splints, in the case of the lungs this is quite impossible, and rest can only be obtained approximately by absolute recumbency, together with abstention from talking, laughing, coughing, and so on. Even rest such as this does not rest the lungs so much as might appear, as anyone can realise for themselves by noting subjectively the actual movements of the thorax when lying as quietly as possible in bed. It may be remarked here that the strain of the uncontrollable and useless cough peculiar to, and coincident with, the first laying down of tubercles in the lung before there is any expectoration, is a sufficient strain on the laryngeal structures without having superadded the strain of talking. As a rule, it will be found impossible to carry out this method of treatment except in a properly constructed sanatorium with single bedrooms, and where the staff is sufficient to allow any or all of the patients to lie in bed if necessary.

If rest of a graduated kind together with good food, are the chief means we possess for bringing about a cure, the precise climate in which a sanatorium is erected will be a matter of comparative unimportance. It will, however, be found that if a patient has been allowed to develop extensive disease or has bronchitis or laryngeal disease, especially if a mouth breather, that is to say, where the lesions speedily come into contact with freshly in-drawn air, that wintering abroad in some comparatively mild and moist climate will greatly benefit the condition, and by allaying the cough may promote healing. The only way that such a climate can be produced in this country on certain winter days is by means of a fire which does not unduly dry the air, together, if necessary, by preventing too large an entrance of the outside atmosphere.

The sending of phthisical patients abroad should never be encouraged without very careful consideration, and when one hears of a patient going to Egypt for treatment, one is scarcely surprised to hear of his premature death in South Africa some months later. I should therefore before closing like to recommend to the more wealthy sufferers from this disease, who in some respects resemble Naaman the Syrian, the advice of his servants when he said, "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? may I not wash in them, and be clean?" "And his servants came near, and spake unto him, and said, My father, if the prophet had bid thee do some great thing, would'st thou not have done it? how much rather then, when he saith to thee, Wash and be clean?" Rest and be cured.

Ayrshire Sanatorium, New Cumnock.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Auto-inoculation versus Hetero-inoculation.

A MEETING of this section was held on March 23rd, Dr. T. H. GREEN being in the chair.

Mr. E. C. HORT read a paper entitled "Auto-inoculation *versus* Hetero-inoculation in the Treatment of Established Infective Disease in Pyrexial and in Apyrexial Conditions, as controlled by (*a*) Clinical Observation, and (*b*) Estimation of the 'Antipyretic' Index." He said in regard to immunity and infection that the practice of inoculation with immune serums and bacterial vaccines, as at present employed, was based on the assumption that in fighting infective disease the tissues had only to contend against extracellular forces such as bacteria and their products. No provision, therefore, whatever was made for antagonising such intracellular enemies to the tissues as autolytic and other enzymes and the products of their activity. This neglect of the intrinsic factors in infection explained the failure of bacterial vaccines in tuberculosis and other serious infections, and the futility of expecting such purely bacteriotropic bodies as opsonins to afford a satisfactory basis for gauging immunity response. In 38 out of 51 opsonic estimations of tuberculous serums no two observers could agree as to what the opsonic index actually was. Opsonic estimations were also unnecessary in pyrexial cases, because if temperature charts were examined in the way he suggested they practically became immunity curves. All cases of tuberculosis with fever fell into one of three main types of curves—(1) cases with response greater than intoxication; (2) cases with intoxication greater than response; and (3) cases with intoxication and response equally balanced. *In cases exhibiting Curve 1 the* prognosis was excellent owing to effective spontaneous auto-inoculation. In such inoculation was unnecessary. In cases exhibiting Curve 2 the prognosis was bad and inoculation dangerous. Some cases exhibiting Curve 3 were ideal subjects for inoculation, but as tuberculin injection made no provision for meeting intracellular needs it ought to be condemned in cases with [illegible] inoculation, on the oth[illegible] ment for such cases if [illegible] Whenever cure of tuberculosis and other infections naturally occurred it was only by spontaneous auto-inoculation that the disease was arrested. This arrest was brought about by restraining all the factors in infection, the intracellular as well as the extracellular. Charts showing successful treatment of pyrexial cases of tuberculosis were exhibited. Variations of the antitryptic index of tuberculous and other serums were then referred to and it was claimed that in apyrexial cases the method of estimation introduced by Golla would prove to be of great value. The fact that the antitryptic index underwent variation in diseases where cellular changes were the chief factors as distinguished from those in which the bacterial element was predominant in which it was also raised, afforded proof to some extent of the views he propounded. A list of diseases in which such variations occurred was given.

Dr. D. LAWSON (Nordrach-on-Dee) said that the temperature by itself was not a trustworthy guide to the advance of tuberculosis and he protested against the temperature chart being exalted into a fetich; he advocated the consideration of broad clinical facts and a wider basis of observation.

After Dr. F. PARKES WEBER had spoken Mr. HORT replied.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Pernicious Vomiting of Pregnancy.—Primary Ovarian Actinomycosis.—Primary Carcinoma of the Vagina.

A MEETING of this section was held on March 12th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. R. DRUMMOND MAXWELL read the clinical account of a fatal case of Pernicious Vomiting of Pregnancy in a primigravida, aged 26 years. The chief features of interest in the case lay in the difficulty of diagnosis, since the patient after admission to hospital ceased vomiting, and there was only the history of severe vomiting at home, unassociated, however, with marked wasting. The toxic nature of the case did not reveal itself in any characteristic alteration of the urine; there was no albuminuria; the only ominous signs on admission were drowsiness and a very rapid weak pulse; there was no jaundice. *The patient passed successively through stages* of restlessness, delirium, mania, and final coma. A necropsy revealed hyaline degeneration and necrosis of the central cells of the hepatic lobules, the kidneys also showing a severe parenchymatous nephritis; sections of both tissues were shown under the microscope.

Dr. F. E. TAYLOR and Mr. W. E. FISHER communicated notes on a case of Primary Ovarian Actinomycosis, a full account of which will be found in THE LANCET of March 13th, p. 758. They pointed out that actinomycosis of the ovary constitutes one of the curiosities of gynæcology, only six cases of this condition being on record. In none of these had the ovary been the primary seat of infection, but had been infected by extension of the disease originating either in the intestines or in the vagina, uterus, or Fallopian tubes. The patient was a single woman, aged 34 years, and was admitted into the Chelsea Hospital for Women in June, 1908, complaining of abdominal pain. The periods were very irregular and very profuse. Pain was first noticed three and a half years before and soon after she became troubled with night sweats, which had continued up to the time of admission to hospital. The right ovary was found to be enlarged. The patient declined operation at this time. Pain and discomfort continued intermittently and at one time she passed blood and pus in the urine. Marked anæmia and loss of flesh finally led the patient to enter the hospital. She was then found to have a tumour of the size of a child's head, which filled the pelvis. There was no tenderness, but the tumour was fixed. The temperature was raised. The tumour was removed, when it was found to be very adherent to the surrounding parts. Both Fallopian tubes were occluded and bi-lateral salpingo-oöphorectomy was performed. The patient for a time was very ill, but she ultimately recovered and left the hospital with a small sinus. Shortly after a large abscess burst and a large amount of pus escaped through the sinus. The patient at the present time is fairly well with hardly any discharge. The microscopical examination showed masses of streptothrix.—Professor R. F. C. LEITH said that the specimen shown was a good example of ovarian actinomycosis caused by the streptothrix actinomyces, but caution must be exercised before accepting the contention of Dr. Taylor and Mr. Fisher that the disease was primary in the ovary. He referred to a case investigated by him in which the ovary and part of the tube were affected. The rectal wall was thickened and in the dense fibrous adhesions binding it to the ovary there were plentiful actinomyces growth. Colonies were also found in the rectal wall and in the wall of the descending colon. *His interpretation of this* case, though still *sub judice*, placed the primary disease in the intestine, from which it had spread to the ovary, the intestinal lesions subsequently cicatrising and healing. He ventured to suggest that a similar interpretation might be placed upon the present case. One of the chief characteristics of this disease was the formation of a local lesion at or near the site of entrance and a spread therefrom by direct continuity of tissue. Spread by the blood stream did take place, particularly the portal blood stream, but this was characteristically a late method of extension.—Dr. W. S. A. GRIFFITH and Dr. T. G. WILSON also discussed the case.

Dr. H. RUSSELL ANDREWS read notes of a case of Primary Carcinoma of the Vagina, in which the uterus and the whole of the vagina were removed. The patient, a multipara, aged 62 years, had a carcinomatous ulcer, the size of a two-shilling piece, high up on the posterior vaginal wall. The cervix was free from carcinoma. *The whole vagina was* dissected out from below, and removed together with the uterus. At an early stage of the operation the vagina was converted into a closed bag by clamping with forceps bent at a right angle, with the object of preventing infection of the raw surfaces by carcinoma cells. The peritoneal cavity was closed by sutures, and the cavity between the rectum and [illegible] The patient was quite well whe[illegible] 18 months after operation. [illegible] J. McCANN described similar cases upon which they had operated. Dr. McCann's patient was free from recurrence when last seen four and a half years after the operation. Dr. McCann had seen five examples of primary cancer of the vagina.—Dr. H. MACNAUGHTON-JONES referred to another case of primary carcinoma of the vagina. Seeing the very few cases of primary carcinoma of the vagina recorded in British literature, he had sought for some statistics from abroad. From all these sources he had only been able to collect 23 instances of primary disease.—Dr. A. H. N. LEWERS said he was surprised to find that some of those present considered this condition very rare. He had himself seen, speaking from memory, at least 15 or 20 cases of primary carcinoma of the vagina. In none of them, however, was the disease at a sufficiently early stage to induce him to attempt a radical operation, and he had therefore been obliged merely to scrape and cauterise the growth in such *as had seemed* to require some active treatment.—Dr. RUSSELL ANDREWS replied.

OTOLOGICAL SECTION.

The Problem of Vertigo.

A MEETING of this section was held on March 6th, Dr. PETER McBRIDE, the President, being in the chair.

Mr. SYDNEY R. SCOTT read a paper entitled "The Problem of Vertigo: Some New Data obtained in a Research into the Functions of the Semicircular Canals in Relation to Movements of the Eyeball in the Human Subject." He gave an account of his observations on this matter based upon an examination of nystagmus and eye-movements associated with giddiness in a large number of patients with diseases of the ear. He had adopted the caloric and rotation tests introduced into clinical otology by Robert Barany and had had opportunities of testing cases both before and after the internal ear had been destroyed by disease or operation. Various forms of nystagmus were recognised and the labyrinthine type was fully described together with Mr. Scott's own views of its mechanism. He had found on completion of his research, which extended over a long period, that his observations confirmed those of Mach, Breuer, and Barany, and he presented some new hypotheses to explain the phenomena observed. The mechanism of the stimulus in cases of nystagmus associated with labyrinthine fistula, whether spontaneous or induced, by metal compresion or other means, was described. Some new data were presented in connexion with so-called ablation nystagmus—i.e., persistent nystagmus of true labyrinthine type after removal of one labyrinth, the other labyrinth being normal. Mr. Scott asserted that he had been able to arrest this form of nystagmus by compression of the common carotid artery. The mechanism of the stimulus was accounted for on the assumption of impaction waves from the internal carotid artery in the carotid canal being transmitted to the labyrinth and ampullary apparatus of the semicircular canals. The hypothesis was put forward with a number of facts supporting it and Mr. Scott submitted that if his observations could be substantiated by competent observers the hypothesis would have a much wider application than he had dealt with in his communication. The paper was illustrated by serial sections of the human labyrinth prepared by Mr. Scott and displayed by means of the epidiascope. A demonstration was given of glass models representing the human membranous semicircular canal and utricles.

Sir VICTOR HORSLEY led the discussion and said that in Mr. Scott's investigations and views he conceived a new basis for considering some of the many obscure features of vertigo. He (Sir Victor Horsley) was interested to find his own observations on monkeys substantially confirmed by Mr. Scott's work on the labyrinth in children and he gave the meeting an interesting account of certain forced movements of the head which followed operations on the labyrinth in apes. He hoped that Mr. Scott would give an account some time of head movements associated with nystagmus in human subjects.

The following members took part in the discussion: the PRESIDENT, Dr. URBAN PRITCHARD, Dr. J. DUNDAS GRANT, Dr. ALBERT GRAY, Dr. HENRY J. DAVIS, Mr. E. B. WAGGETT, Mr. C. E. WEST, and Mr. WHITEHEAD, and Mr. SCOTT replied.

MEDICO-LEGAL SOCIETY.

The Difficulties and Abuses of the Workmen's Compensation Act.

AT the meeting of this society which took place on March 23rd, Mr. Justice WALTON, the President, being in the chair, an adjourned discussion took place on Mr. A. S. Morley's paper, "The Difficulties and Abuses of the Workmen's Compensation Act." After Mr. MORLEY had given a brief *résumé* of his paper, Dr. R. J. COLLIE opened the discussion with a paper detailing in strong terms the abuses under the Act known to exist, quoting various authorities in support of his views, and stating that the insurance companies were seriously considering the question of medical examination of every person underwritten by them before accepting the risk of insurance. If that took place it was not difficult, said the speaker, for the most unimaginative to see that the ranks of the unemployed would be augmented by tens of thousands. Sick benefit societies were feeling severely the strain produced by the demoralisation of unduly prolonged sickness and of deliberate malingering. Unless speedily amended the Act as it now stood, instead of being the Magna Charta of the working man, would inflict grave hardships on a very large proportion of the working men of this country. In considering the causation of the abuses Dr. Collie stated that some expert medical witnesses relied too much on the claimants' statements and that others were untrustworthy because their fees depended upon the issue of the case. Both these points he made in very clear and strong language. With regard to the remedy, he said that if two words only in the first schedule of the Act were altered there would be a huge slump in bogus cases, in hard swearing, in prolonged litigation, and in the degradation of the working classes. Section 15 of that schedule enacted that a county court judge might refer the matter to a medical referee "on application being made to the court by both parties." He suggested that the words "either party" be substituted for "both parties." That would make all the difference in the world. It was well known, and very significant, that neither a workman nor his solicitor would agree to remit a case to the medical referee. Further, if Section 5 of the second schedule, which enacted that "a judge may, if he thinks fit, summon a medical referee to sit with him as an assessor," were altered to read, "a judge shall, on demand of either party, summon a medical referee to sit with him as an assessor," then much of the wickedness which he had endeavoured to expose would be a thing of the past.

Dr. F. J. SMITH thought that too much weight was given to the class of witness known as the medical expert. The position of a medical referee would be a much more independent position than that of the medical expert.

His Honour Judge SMYLY said that no doubt there were many doubtful cases under the Act, but, on the other hand, there were a vast number of cases that never came into court, being amicably settled. If that was considered it would be found that litigation under the Act was not so great in proportion as most people thought, and consequently those cases which were taken to court were the doubtful and suspicious ones and required looking into. If a medical referee was present in every case it would be a great assistance. He had suggested that medical questions should go to the medical referee before coming to the judge. To both workman and employer there would be a great saving of expense.

His Honour Judge BRAY thought that in many cases a medical man would be a great assistance to a judge as assessor, because he had to admit that one might be taken in by some of the expert medical evidence. On the other hand, there were cases in which it would be a farce to accept absolutely the opinion of the assessor and to disregard the medical evidence.

His Honour Judge HOWLAND ROBERTS stated that there were many cases of very great difficulty in which there was a conflict of evidence given by apparently respectable and experienced medical men. He had received great assistance from a medical assessor sitting with him, but it would not do for a judge to lean entirely upon a medical assessor, for to some extent he should be guided by the medical evidence.

Dr. S. B. ATKINSON, Mr. M. J. FINUCANE, Mr. W. E. SINGLETON, and Mr. W. V. BALL having spoken,

Mr. Justice WALTON said that since he had been a judge he had done all he could to promote trial with assessors, not merely in medical cases, but in other cases where scientific questions arose. Judging by what he had heard that evening it appeared to him that it would be a better arrangement if county court judges were able to appoint a medical referee or medical assessor—the two were different although working somewhat in the same direction—on the application of either party. With the county court judges present he agreed that there were a great many doubtful cases that came before the courts. Often it was extremely difficult to decide which was the right view, some witnesses honestly taking one view and others the opposite. Moreover, some extraordinary claims were made when it was quite evident that no injury had been sustained at all in the ordinary sense.

The meeting passed the following resolution:—

> That the council be asked to appoint a committee to consider and report what action, if any, the society should take in the matter of the alleged unsatisfactory working of the Workmen's Compensation Act.

The proceedings then terminated.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on March 12th, Dr. A. R. PARSONS, the President, being in the chair.

Dr. JAMES LITTLE exhibited a specimen of Bronchiectasis from a man, aged 25 years. He was taken to hospital after a fortnight's illness at home. He was extremely short of breath and livid. Later he became breathless to the last degree, and had the peculiar hue which Dr. Hudson used to say was a fatal hue in heart disease—that due to a mixture of unaerated blood and jaundice. He lived three days afterwards. His temperature was never elevated and his pulse was always feeble. Six years previously, when in hospital with scarlet fever, it had been noticed that his heart was beating considerably to the right. When Dr. Little had examined him he found the sounds over the back of the right chest were those of large cavities in the lungs. Over the lower lobe of the left lung there was dulness on percussion. At the necropsy the heart was found dragged to the right side by pleural adhesions. Pneumococci were found in the sputum during life. The lower lobe of the left lung was extremely congested and the cause of death appeared to be pneumonia. The right lung presented immensely dilated bronchial tubes in every part. The auriculo-ventricular orifices of the heart were much dilated. The left ventricle was considerably dilated and hypertrophied. The right ventricle was extremely dilated and somewhat hypertrophied. The patient brought up a large quantity of purulent sputum, but it was not offensive in smell, which was very strange, as he could hardly conceive a lung less able to expel sputum before it decomposed.—Sir JOHN MOORE said that if the bronchial tubes were dilated throughout the entire length, there was less likelihood for putrefaction and consequent fœtor to occur than if dilated through only a portion of their extent.

Dr. J. B. COLEMAN exhibited a Frontal Sarcoma from the brain of a woman, aged 25 years. The symptoms had lasted for six months and had given no localising indications. The tumour had been circumscribed.

Mr. W. I. DE C. WHEELER exhibited organs from a case of Polyserositis. The patient, a man aged 34 years, had been sent from Galway with a large ascites. He was fairly healthy and had no other symptoms. Two years previously he had had his right pleura tapped and when he went to hospital a small left pleural effusion was found and tapped. The ascites increased in hospital. Ten days after admission the abdomen was opened. Covering the liver there was a thick capsule, and over it there were little depressions as if peas had been pressed into the surface of it. The liver was not cirrhosed. There were adhesions between the great omentum and the abdominal wall. The Talma-Morison operation was performed. No signs of tubercle were found, and there was no growth of any kind. The operation seemed to relieve the ascites and he lived eight weeks. He was only tapped once after it, and a very small quantity of fluid was found.—Dr. W. G. HARVEY described at length the post-mortem appearances of the viscera. The organs, with the exception of some congestion and parenchymatous degeneration in the liver and kidneys, were healthy, while their serous coverings were immensely thickened and such serous cavities of the body as were not totally obliterated were distended with fluid. There was absolutely no evidence of tuberculosis either in the sections or as a result of inoculations of guinea-pigs with the fluid.

Dr. J. F. O'CARROL and Dr. H. O. EARL exhibited and described specimens from a case of Pharyngeal Diphtheria and of Heart Disease.

SECTION OF SURGERY.

Exhibition of Cases and Specimens.

A MEETING was held on March 19th, Mr. E. H. TAYLOR being in the chair.

Mr. P. J. DEMPSEY exhibited a case of Lateral Pharyngotomy. The patient had consulted him for hoarseness. He had no pain, but his voice got tired more easily than it ought, and he had a sensation of something in his throat. On examination, by merely depressing the tongue on the right side the beginning of a small pear-shaped swelling was to be seen, corresponding almost identically to the posterior pillar of the fauces. The growth was found to extend down into the epiglottis. On palpation there was evidence of fluid and it appeared to be a branchial cyst. The patient, who had to use his voice in preaching, decided to have an operation. If the cyst were branchial it would probably have diverticula in various directions and could not be got at from the inside. He therefore thought it best to take it away from without. The operation was performed on Nov. 26th as if it were a lateral pharyngotomy, although the pharynx was not opened. When he opened the cyst about two tablespoonfuls of clear fluid came out. The wall of the cyst was curetted and packed with gauze, which was kept in for 48 hours and then removed and a drainage-tube inserted. The tube was kept in for about a week. No fluid came and there were no signs of the cyst refilling. The recovery was uneventful. The patient had pain on swallowing after the operation which disappeared in a few days. He had no trouble since with his voice.

Mr. R. H. WOODS exhibited a case of Extirpation of the Larynx for Carcinoma, with new apparatus for voice production. The patient, a man, aged 42 years, had consulted him two months ago complaining of pain in swallowing. On examination there was a large tumour, occupying the right half of the larynx and extending up to the middle line, which proved on microscopic examination to be a squamous carcinoma. Eight weeks ago, assisted by Mr. Taylor, he opened the region of the carotid sheath and dissected out obviously carcinomatous glands. The glands were adherent, and a couple of inches of the internal jugular vein were excised on the right side. After a preliminary tracheotomy the larynx was opened, and as there was little chance of a hemilaryngotomy curing the case, the whole larynx was extirpated. The trachea was sutured to the skin and the sac of the pharynx completely cut off from communication with the respiratory tract. In order to enable the patient to speak it occurred to him that he might be able to convert the sound made by a reed into speech. Accordingly he fixed a reed in a tube. By putting it into the nose and dropping it over the soft palate, and by putting the other end into the trachea he was able to blow and make the reed vibrate. A valve was used to take in the air and when he had his chest full he put his finger to the end and the air was pressed into the tube. Mr. Woods then inserted the instrument and the patient, after a salutation to the section, counted from one to ten.—Mr. P. DEMPSEY, Mr. W. L. MURPHY, Mr. TAYLOR, Mr. A. J. M. BLAYNEY, and Mr. H. STOKES discussed this very instructive case, and Mr. WOODS, in replying, said that before doing the extirpation he thought it wise to give the patient an antistreptococcus vaccine so as to raise his opsonic index, and his temperature only rose to 100° F. for two days and then fell to normal. This was, in the circumstances, remarkable, and he thought that some of the credit was due to the preliminary vaccination.

Mr. MURPHY exhibited a Rhinolith removed from a woman. [illegible]

Mr. TAYLOR exhibited an Ectopic Hydronephrotic Kidney removed from a young woman about a fortnight ago. The clinical symptoms were strongly indicative of appendicitis. On palpation over her right iliac fossa he was able to determine deep fluctuation, and as she appeared to be very ill he decided to operate that evening and to cut down over the fluctuating area with local anæsthesia. He was surprised to reach the parietal peritoneum without any evidence of pus. When he opened it his finger passed over a surface which was bigger than a normal cæcum and he thought that it might be an ovarian cyst with a twisted pedicle. He extended the incision under chloroform, but found no pedicle. He punctured a large swelling which was fluctuating and tense and a quantity of fluid escaped. The tissue at the edge of the opening was evidently renal. He put a tube into the kidney and drained the hydronephrosis, and after ten days removed the kidney, having previously satisfied himself that the left kidney was healthy. The case showed that even where all typical features of appendicitis were present they might come on a case that had nothing whatever to do either with the cæcum or appendix.—Dr. W. S. HAUGHTON, Mr. BLAYNEY, and Dr. G. PEACOCKE discussed the case, and Mr. TAYLOR replied.

Dr. HAUGHTON exhibited a specimen of Sarcoma of the Orbit and Upper Jaw from a girl aged about 28 years. He described the clinical history and the operation which resulted in an uneventful recovery. He also exhibited a specimen of apparent Carcinoma removed from the breast of a man aged 56 years. The diagnosis awaited confirmation by the microscope.

[illegible] ng of thi [illegible], the Pre [illegible] r and Dr. R. W. MacKenna showed the following cases: 1. Favus affecting the thighs and legs of a steward from an emigrant ship. The scalp and other parts of the body were free. 2. Rodent Ulcer treated successfully with zinc ions. 3. Psoriasis of the Face occurring in women. 4. Psoriasis in a man accompanied by Sycosis. 5. Lupus Erythematoides. 6. Syphilitic Pemphigus Neonatorum. 7. Dermatitis following the use of a proprietary ointment. 8. Wax Casts modelled from cases under their own care, illustrating the cutaneous lesions of syphilis.—Dr. J. R. Logan showed a case of Bilateral Asymmetry which he regarded as hypertrophy of the whole of the right side. The child was 15 months old and the difference had been noticed since birth. During the last five months the right side limbs had grown more than the left but the head had become more symmetrical.—Dr. C. E. P. Forsyth read a note on the Presence of Tubercle Bacilli in the Blood in Tuberculosis. The blood of 12 patients was examined. Ten of these were undoubted cases of pulmonary tuberculosis and in all the organism was found in the blood. The blood was drawn from a vein in the arm. In one case phagocytosis was noticed and only in one was there any evidence of mixed infection. None of the cases was a rapidly progressing case nor a case of general tuberculosis. Of the two cases in which no bacilli were found one patient was probably not tuberculous and the other had physical signs of phthisis but no bacilli in the sputum. These cases went far to confirm Rosenberger's observations, for example, as to the use of vaccine therapy, in this disease.—Dr. Henry H. Clarke read a note on Three Years' Experience in the Use of Tuberculin. His conclusions were: (1) That tuberculin was best administered by the German intensive method, the dose being given at short intervals of one to two days, and rapidly increasing up to one to two cubic centimetres of the original solution; (2) that doses given by the mouth had the same effect as when given subcutaneously; (3) that the temperature and clinical conditions were as delicate a guide to treatment as the opsonic index; (4) that new tuberculin (bacillus emulsion) was the most effective preparation; (5) that it should be prepared from human bacilli in dealing with disease produced by these bacilli; (6) to determine the variety of bacillus he recommended von Pirquet's cutaneous reaction; and (7) he considered tuberculin a useful drug but not a substitute for good food and fresh air.—Dr. J. Hill Abram referred to a case which he reported ten years ago in which the patient completely [illegible] [illegible] treatment with tuberculin T.R.; subsequent [illegible], [illegible]ever, had not confirmed him in its use. He [illegible] [illegible] [illegible]ier that inoculation experiments had estab[illegible] [illegible] [illegible] distinction between the bovine and human varieties of tubercle bacilli. He advocated a further trial of tuberculin treatment on the German intensive lines.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 26th, Dr. B. G. Morison, Vice-President, being in the chair.—Mr. Elmore W. Brewerton read a paper on Convergent Strabismus and its Treatment. He said:—Donders was the first to advance the theory that the onset of convergent concomitant strabismus in children was due to errors of refraction. Accommodation and convergence are normally closely associated, and in hypermetropia an excessive amount of accommodation is necessary for distant vision. There is in such cases, therefore, a tendency to excessive convergence. Children are generally hypermetropic and on this account alone show a slight tendency to convergent squint. Their great safeguard is the development of binocular vision, and this latter has to be acquired, and if anything prevents its acquisition convergent strabismus is extremely probable. Binocular vision in its complete sense is the psychical blending of two slightly dissimilar objects so that an effect of *solidarity* is given to the object, and its relation to surrounding objects can be appreciated. In examining children with no apparent squint binocular vision should always be tested. If this is present and well developed no permanent squint will ever appear, and if a history of occasional squint be given it is quite certain that the correction of errors of refraction will correct the squint. The squinting eye is commonly amblyopic—that is to say, it has very defective vision without any apparent cause. There can be no doubt that the vision of a squinting eye can deteriorate for want of use, or rather from active suppression of the image, and this must have a depressing effect on the ocular centres. But, on the other hand, when a squint develops before the age of three years it is practically certain that the vision is far short of perfect. As regards treatment of squint, in all cases errors of refraction must be treated under atropine, and when possible binocular training adopted. If after 12 months in the continuous wearing of proper glasses the squint is as bad as ever operation ought to be urged, and to give a fair chance of developing binocular vision the operation must be performed early, preferably about the age of five years. If operation is decided on, the kind of operation must depend chiefly on the amount of squint present: for 15° advancement of one external rectus, for 30° advancement of both external recti, for 45° advancement and tenotomy of one eye, followed a week later by advancement of the other. After every operation both eyes to be tied up for seven days; then both eyes uncovered and glasses put on and atropine used for a further ten days. The later the squint appears the better a chance of good result, because binocular vision has almost certainly been partly developed before the squint commenced. The worst cases are those who began to squint soon after birth.—Dr. Morison showed a man, aged 45 years, with abnormal Valvular Disease, the murmurs being double aortic and pulmonary.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held on March 11th. A special general meeting preceded the ordinary business, when it was decided that in future the ordinary monthly meetings of the society are to be held at 8 P.M. instead of at 6.30 P.M.—The following cases were brought before the meeting:—Dr. J. D. Wardale: Tumour of the Eye for Diagnosis.—Dr. David Drummond: 1. A Typical case of Acromegaly in a Coal-miner, aged 40 years. Up to 19 years of age he was quite normal, but since the age of 21 he had observed comparatively little change. He suffered from headache, but there was no vomiting or visual defect. There was no sugar in the urine. 2. A male child, aged seven years, who had a Chronically Distended Bladder which occupied the greater part of the abdomen.—Dr. R. A. Bolam: (1) Lupus Erythematosus of the Scalp; and (2) Lupus Erythematosus of the Face and the Hands, complicated by Psoriasis.—Dr. T. Beattie: (1) a case of Staphylococcus Aureus Infection of the Blood treated with a Vaccine; (2) Gonorrhœal Arthritis in a Male treated with a Vaccine; and (3) a case of Osteo-arthritis due to the Gonococcus. The infection dated nine years back. There was a typical osteo-arthritis of the knee-joint.—Mr. H. B. Angus: 1. A man after Recent Removal of the Scapula for Sarcoma. Mr. Angus had left the acromion and coracoid processes, which he thought was an improvement. 2. A patient with an Old Fracture of the Femur with an Unreduced Sciatic Dislocation of the Hip-joint. An attempt was made to reduce it three months later, but the bone was again broken. An open operation was carried out, but it was found impossible to reduce the dislocation, so the head of the femur was removed.—Dr. W. E. Hume: (1) A case of Bulbar Paralysis; and (2) a Cretin, aged 16 years, who presented the appearance of an infant aged two years. The administration of thyroid extract improved it as regards its limited intelligence and the condition of the skin.—Mr. John Clay showed specimens of Excised Gall-bladders. He took a very moderate view of the operation of cholecystectomy and thought that the main indication was a gall-bladder which had a stone impacted in the duct with the presence of clear mucus. He also urged the importance of not removing the gall-bladder if there was any chance of a permanent obstruction of the common bile-duct.—Dr. A. Parkin showed a typical case of Congenital Heart Disease.—Mr. A. M. Martin exhibited (1) a case where a Splenectomy had been performed for Wandering Spleen; and (2) cases after Rupture of the Knee-joint Cartilages.—Dr. George Hall demonstrated a good example of Disseminated Sclerosis.—Mr. W. G. Richardson read an interesting paper upon Post-operative Tetanus.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 19th, Dr. T. K. Monro, Vice-President, being in the chair.—Dr. A. Freeland Fergus showed a number of photographs of cases and a patient on whom he had performed his operation for Ptosis. The operation consisted in the resection of the tarsus and of excision of a large part of it with the suturing of the remaining portion to the occipito-frontalis muscle. With this operation the patient had considerable power both of shutting and of opening the eyelid. He pointed out that the operations of Worth and Harman were essentially good but that they ligatured the lid permanently open. The operation of Hess, although differing in principle from these operations, also permanently fixed the eyelid in an open position. Pagenstecher's operation was one which he considered should never be performed. Cicatrical contraction by the introduction of thread sutures could, in his opinion, only take place when the sutures were not perfectly sterile.—Dr. W. S. Syme made a communication on Some Points in the Surgery of the Sphenoidal Sinus, based on an examination of 155 adult skulls. The average distance from the anterior nasal spine of the maxilla to the opening of either sinus was $2\frac{1}{2}$ inches, the extremes being $2\frac{1}{8}$ inches to $2\frac{3}{4}$ inches. To the posterior wall the average on the right side was $3\frac{1}{8}$ inches and on the left $3\frac{3}{16}$ inches, the extremes being from $2\frac{3}{4}$ inches to $3\frac{3}{4}$ inches. In only one-sixth of the skulls was the posterior wall distant less than 3 inches, and in none was the opening distant as much as 3 inches. As a rule the posterior ethmoidal cell did not extend beyond the anterior wall of the sphenoidal sinus. Well-marked osseous septa within the sinus were found in 13 cases. Suppuration in these cavities, he considered, was much more common than was generally supposed.—Mr. J. Hogarth Pringle read a paper on the Treatment of Fractures of the Long Bones. He advocated Bardenheuer's method of extension by very heavy weights, sometimes as much as 35 pounds, applied so as to correct lateral displacement and rotation as well as shortening.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 16th, Dr. J. J. Cox, the President, being in the chair.—Dr. P. R. Cooper reported a c [illegible] ks after delivery c [illegible] seen in the first p [illegible] ine at the sixth month. She had eclamptic seizures at full term and was delivered of a living male child, after which the fits ceased and the albuminuria disappeared. The second pregnancy terminated at seven months and she was delivered of a stillborn child. There were no fits and no albuminuria. Nine days after the patient had some paresis and her mental condition was somewhat clouded. 21 days after confinement she came downstairs, when she vomited and became drowsy. Later albuminuria set in, followed by coma. The usual treatment was followed by no improvement. Lumbar puncture was then performed, from two to three drachms of cerebro-spinal fluid being drawn off, and saline injected under the breasts. Two days later lumbar puncture was repeated, and a further two to three drachms of cerebro-spinal fluid withdrawn. After this the fits ceased and the patient made a gradual recovery.—Dr. E. S. Reynolds made some remarks on the Diagnosis and Treatment of Migraine. He drew particular attention to the more unusual varieties of auræ that might precede the typical headaches. Numbness and tingling in the fingers occurred not infrequently. Transient paralysis of the muscles supplied by the third nerve was a rare form described by Charcot, and a case was cited illustrating this variety. As regards treatment, the synthetic drugs were of paramount importance; antipyrin was usually the most valuable, but some patients responded better to phenacetin, aspirin, or pyramidin. The drugs must be exhibited early in the attack to be efficacious.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A special meeting of this society was held on March 19th to discuss the question of the giving of certificates to hospital out-patients, Mr. R. F. Jowers, the President, being in the chair.—The following motion was proposed by Mr. H. H. Taylor and seconded by Dr. Walter Broadbent, and was passed with only two dissentients:—

[illegible]

should be given.

GUY'S HOSPITAL: THE GULL STUDENTSHIP.—The Gull Studentship in pathology and allied subjects is vacant. The studentship is open to candidates under 30 years of age who have studied in the medical school of Guy's Hospital, is of the annual value of £150, and is tenable for three years. Further particulars may be obtained from the secretary of the board of electors, to whom application must be addressed at the office of the medical school not later than April 17th next. The elected student will be expected to commence work on May 1st.

Reviews and Notices of Books.

The Principles of Hygiene as Applied to Tropical and Sub-Tropical Climates, and the Principles of Personal Hygiene in them as Applied to Europeans. By W. J. R. SIMPSON, M.D. Aberd., F.R.C.P. Lond., D.P.H., formerly Health Officer of Calcutta and Lecturer on Tropical Hygiene at the London School of Tropical Medicine. London: John Bale, Sons, and Danielsson, Limited. 1908. Pp. 396. Price 15*s*. net.

Professor Simpson has by the publication of this work rendered more feasible the improvement of our methods of sanitation in India and the tropics generally. Hitherto no work of authority has been published with quite this scope. Although the principles of hygiene are the same in the tropics as in colder climates, yet they are in truth modified by the differences in temperature, food, mode of life, environment, and civilisation found in the former, and consequently the practice of hygiene in the tropics is in many respects different from that pursued in colder climates, and the methods pursued have to be adapted to their particular circumstances. Non-recognition of this need of adaptation to the varying conditions met with will account for the frequent failures in the application of hygienic principles. For example, water-sealed traps properly ventilated are not equally useful in the tropics and in temperate regions as guardians against gas from sewers gaining access to the dwelling houses. Similarly, English types of latrines are seldom adapted to the habits of Eastern peoples. Other obvious points, among many that have to be considered, are the modification of the methods of the purification of water, the question of food, and the relation of insect life to the dissemination of disease.

The work opens with a discussion on warm climates and the necessary personal hygiene therein. The remarks on food and drink are excellent and those on clothing and bathing represent the fruits of experience, though the reason for some of the rules is not obvious. The author in the next four chapters discusses fully the question of water-supplies. The principles of diet and the construction of dietaries are next considered and are fully up to date, Chittenden's researches in this respect being relied on. The relation of food to health and disease is succinctly debated, and an excellent *résumé* of the bearing of diet on the etiology of beri-beri is given, the various theories on the subject being all set out. Other diseases connected with diet in the tropics, such as lathyrism and pellagra, receive detailed attention as well as the various parasites in food which cause disease. Again, the author pertinently shows how a not uncommon source of illness amongst the native population is the keeping of food which has been cooked overnight, or in the early morning, for meals of the next day in order to save fuel. The food thereby becomes decomposed, or from long standing amidst insanitary conditions absorbs or has had added to it foul emanations or infectious material. The facts in relation to the infection of meat are concisely described, as are the post-mortem appearances appertaining to the several disease conditions that may be met with.

Dr. Simpson next passes to the collection, removal, and disposal of waste matters. The early removal of all such matters from dwellings in the tropics is rendered necessary by these waste products undergoing a far more rapid decomposition in warm than in temperate climates. The removal and disposal in a *dry* hot climate will present few difficulties, but far otherwise is it where the climate is both hot and *wet* or in the region of tropical rains. Then the procedure will be much more complicated. The most important of the waste products are, of course, the excreta and sewage: these, as there are as a rule no sewers in villages and small towns, have to be removed by manual labour or cartage. In connexion with this the author considers the amount of excreta to be removed and the number of buckets and carts required for the removal; the protection of the excreta from rain and flood water—in itself a most essential procedure; and latrines and trenches, where he shows how essential it is to keep the solid and liquid excreta separate. The various forms of latrines are described and next the methods employed for removal and disposal of sewage. The Allahabad system of trenching is considered; it is certainly admirable for temperate climates, as was shown by the late Dr. Vivian Poore, but in India it has drawbacks, notably it attracts dangerously large numbers of flies. This may not be of great importance at certain seasons of the year and if the trenching ground be well removed from dwelling houses; and in the hills Colonel H. Hamilton, I.M.S., has found it to answer admirably.

The removal and disposal of sewage by the water-carriage system has a chapter to itself. This system can only be undertaken in large towns provided with drains and sewers. The author points out that the separate system is the preferable one in the tropics, the storm water going direct to the river, whilst the sewage goes to the land to be purified before admission to the river. The various methods of the disposal of the sewage conclude the section. The subjects of the soil and its drainage next claim attention, and then hygiene in relation to streets and houses. The value of these can be easily understood when we recollect the narrow streets, the winding alleys, the crowding together of the houses, the whole forming a highly insanitary labyrinth which cannot be efficiently cleansed nor be purified by a free circulation of air. (What a blessing to health it would be if such a fire as the old fire of London would burn out once and for ever some of the thickly populated foci of disease with which our Eastern possessions abound!) The sanitation [illegible] jails is detailed and good results are shown to be here [illegible] within the powers of the jail superintendents, as the surrounding circumstances are less inimical to health. The last two chapters are on communicable diseases and on the measures to be undertaken against the malaria and the other diseases caused by the mosquito.

From this brief *résumé* of the work a just idea may be gathered of its design and contents and it will be seen that an ever-increasing number of Europeans require exactly the kind of information with which it is packed.

Our Teeth: How Built up, How Destroyed, How Preserved. Described and illustrated by R. DENISON PEDLEY, F.R.C.S. Edin., L.D.S. Eng., Dental Surgeon to the Evelina Hospital for Sick Children, Southwark; and FRANK HARRISON, M.R.C.S. Eng., L.D.S. Edin., Dental Surgeon, Sheffield Royal Hospital, and Lecturer on Dental Surgery and Pathology, University of Sheffield. London: Blackie and Son, Limited. 1908. Pp. 97. Price 5*s.*

IN the preface to this work the authors state that "this book seeks to explain what is unknown to the majority of educated men and women—viz., the causes of dental diseases, the means of preventing them, their effects, and the need for their rational treatment." The task of writing on disease in language understandable by the lay mind is not an easy one, but the authors seem to have overcome the difficulty and have produced a work which can be readily understood by any and all, and which will have the effect of directing attention to the importance of their teeth and cause them to seek dental advice at an early stage. There are, however, a few criticisms we should like to offer, more perhaps in the way of suggestion for future editions. In a few instances the terms used are a little too technical for a work so directly addressed to the public intelligence. We think that the introduction of drawings to show the developing teeth at birth, one year, and perhaps three years of age would impress more vividly in the mind the fact that in the early years of life the permanent teeth are in the process of formation. Perhaps, too, insufficient attention has been drawn to the actual cause of caries and not enough made of the important part that the easily fermentable carbohydrates play in the production of the diseases. Lastly, we think that the rules on the care of the teeth might be made more terse and more dogmatic. In our view it would be difficult to improve upon the short code of rules in use at the Royal Dental Hospital which is as follows: "1. The teeth must be kept clean. 2. Use a small tooth-brush with stiff bristles. Use a little soap and some precipitated chalk. 3. Brush all the teeth thoroughly, especially the back ones. Brush all surfaces of the teeth. 4. Clean the teeth immediately before going to bed. Take no food of any sort afterwards. Clean the teeth again in the morning." Nobody can mistake the meaning of this code, which is saying a good deal when we recollect what mistakes the hospital out-patient can make.

Archives of the Middlesex Hospital. Vol. XII. London: Macmillan and Co. 1908. Pp. 63.

THIS small volume contains clinical papers from members of the teaching staff of the hospital and contributions from the clinical and pathological laboratories. The first of these is by Dr. Comyns Berkeley on Wertheim's Radical Abdominal Operation for Carcinoma of the Cervix Uteri, and includes a report of four cases. This operation, by which the uterus with as much parametric tissue as possible and sufficient of the healthy vagina to encapsule the diseased area are removed through an abdominal incision, is regarded as a striking advance on any method previously proposed for dealing with cancer of the cervix uteri, since it is applicable to a larger proportion of the cases and results in a greater freedom from recurrence. Dr W. Pasteur, Mr. A. G. R. Foulerton, and Dr. H. Maccormac describe their investigation of a case of acute poliomyelitis associated with a diplococcal infection of the spinal sac, this paper being reprinted from THE LANCET of Feb. 15th, 1908. Mr. W. Sampson Handley discusses the operation of Lymphangioplasty, which he first described in THE LANCET of March 14th, 1908, and gives an account of three cases in which he has employed it. He describes the manner of production of the brawny arms in cases of cancer of the breast, which he attributes to the destruction of the lymph vascular system associated with the permeative spread of the growth. He also refers to the reasons which led him to try the use of "silk conduits" for the relief of this painful complication and gives instructions for the performance of the operation. Dr. Reginald J. Gladstone describes two cases of diaphragmatic hernia. The first of these was a diaphragmatic hernia of the "solitary" kidney in an iniencephalic monster, in which there was also an umbilical hernia of a portion of the liver and gall-bladder. The other case was that of an old woman, aged 96 years, with a fatty hernia into the right pleural cavity, and in addition the sac of a small femoral hernia on the right side and also a small obturator hernia of the extra-peritoneal fatty tissue on the same side. The same observer describes a case in which an aneurysm of the arch of the aorta, multiple tuberculous lesions, a perforated ulcer of the intestine, and a hernial sac co-existed in a man who ultimately died from acute lobar pneumonia. These various lesions were found in a dissecting-room subject who had only complained of symptoms three months before death. There were also present an empyema of the lower part of the left pleural cavity and complete blocking of the thoracic duct by a thrombus. Dr. Victor Bonney contributes a paper on the simulation of the symptoms of tubal pregnancy by acute ovarian abscess. He refers to the fact that in cases of ovarian and tubo-ovarian abscess there is usually a history of amenorrhœa and that not infrequently they are wrongly diagnosed as ruptured tubal gestation.

Retinitis Pigmentosa, with an Analysis of Seventeen Cases occurring in Deaf-Mutes. By WILLIAM T. SHOEMAKER, M.D., Philadelphia. With Examinations of the Blood and Urine by JOHN M. SWAN, M.D., Philadelphia. With illustrations and three coloured plates. Philadelphia: J. B. Lippincott Company. 1909. Pp. 106. Price 8*s*. 6*d*. net.

THIS essay, bearing the modest motto "Valeat quantum valere potest," was awarded the Alvarenga prize of the College of Physicians of Philadelphia in 1908. It is an excellent *résumé* of the subject, though perhaps not so exhaustive as might be expected in a thesis of this nature. Commencing with the history and anatomico-pathological characteristics of the disease, it must be remarked that the pathology is very cursorily dealt with. The symptomatology is adequately described, due attention being directed to the occurrence of ring scotoma and its explanation. Under etiology are discussed heredity, consanguinity, syphilis, maternal impression, deaf-mutism, idiocy, and cirrhosis of the liver. The more recent literature on the hereditary aspects of the question appears to have escaped observation, and the undue importance which has been attached to consanguinity is not sufficiently emphasised. The author agrees that syphilis plays no part in the causation of so-called "idiopathic" retinitis pigmentosa. It is not unnatural that some stress should be laid upon the coincident occurrence of deaf-mutism in some cases, and we are inclined to think that the author's purview of the whole question is somewhat vitiated by the limitation of his studies to a specific group of cases. The clinical details of the author's cases follow, but reveal nothing very noteworthy. The investigation of the blood and urine by Dr. Swan is a piece of work which was waiting to be done, and has been done well. It was a rather thankless task, for *a priori* one could expect no striking results, and it proved negative. Amongst the methods adopted we may point out that Baumann's method of estimating conjugate sulphates is open to criticism. It is to be hoped that some competent pathological chemist will turn his attention to the excretion of these sulphates in various diseases—a subject of far-reaching importance which has not to our knowledge been attacked by unequivocal methods in recent years. The book concludes with a chapter on diagnosis and treatment and a bibliography which is far from complete.

The Systematic Relationships of the Coccaceæ, with a Discussion of the Principles of Bacterial Classification. By CHARLES EDWAI
at the
ROGERS WINSLOW. London: Chapman and Hall; New *York: John Wiley and Sons. 1908. Pp. 300. Price* 10*s*. 6*d*. net.

THE problem of the classification of micro-organisms is of practical as well as of scientific importance. Many groups of bacteria have become so crowded with slightly varying forms that some method of grouping these variants has become a necessity if hopeless confusion is to be avoided. The present work is a careful and painstaking attempt to bring order into the family of the coccaceæ. It has for its basis the detailed study of 500 strains of cocci isolated by the authors from various sources, together with an extensive study of bacteriological literature so far as it refers to the cocci. Much use, too, has been made of the investigations of Gordon and Houston and of the important work on the streptococci by Andrewes and Horder. The value of the work of these British observers is fully recognised and acknowledged. The methods employed have been biometrical. In the case of the strains of cocci isolated by the authors they were submitted to 11 definite, and in most cases quantitative, tests and a statistical study made of the results obtained. On the basis of the numerical frequency of characters it was possible to form a conception of the relations of the coccaceæ which led to a classification not too widely different from that previously employed. The organisms were found to separate themselves definitely into a parasitic and a saprophytic group—the para-coccaceæ and meta-coccaceæ. In the first group fall the pathogenic diplococci and streptococci and the staphylococci (albus and aureus). The authors separate, it will be noticed, the diplococci from the genus streptococci, though it is more usual to regard the diplococcus pneumoniæ as belonging to the streptococci (Andrewes and Horder and others). The morphology and cell grouping of organisms, though used as test characters in the study of the various strains, are not allowed to override the indications derived from the other tests. This is seen in the above example, and in the same way, though the genus sarcina is retained to include packet-forming cocci which are regarded as closely allied to the genus micrococcus (Winslow and Rogers), yet a number of cocci, though showing the sarcina arrangement, are included in a new genus, rhodococcus, on the ground of red pigment formation and other characters. It has become rather usual to consider staphylococcus pyogenes aureus and albus as varieties, but they are here regarded as the type organisms of the two genera aurococcus and albococcus respectively. Variations in cultural characters are considered to be too uncertain and too dependent on small changes, physical or chemical, in the nutrient media to be of any service for the purposes of classification. The character of pigment production under definite conditions is, however, considered to be of high value and a quantitative colour chart is prefixed to the book. The general principles of bacterial classification are most excellently set forth in the first chapter. There is a very extensive bibliography.

LIBRARY TABLE.

Pharmacology: The Action and Uses of Drugs. By MAURICE VEJUX TYRODE, M.D., Instructor of Pharmacology in the Medical School of Harvard University. Philadelphia: P. Blakiston's Son and Co. 1908. Pp. 255. $1.50 net.—This book is an attempt to give the facts essential for the medical student's needs without profound scientific discussions of opposite opinions, and the author has rejected vague and contradictory statements which would but confuse elementary students. The classification is not that usually adopted in the run of text-books. Part I. deals with drugs the constitutional action of which is in greater prominence. These are divided into 25 groups, including such as the following: ether and chloral, amyl nitrite, morphine, ammonia, cocaine, hydrastine, quinine, phenol, and so on. In each case the chief actions, uses and therapeutic effects of the drugs are stated, and at the end a short summary of the group action is added by way of emphasising the chief points. Chemical formulæ are conspicuous by their absence, while as regards the materia medica aspect of the groups the doses are given both from the U.S.P. and the B.P. when the drug is described in both Pharmacopœias. We strike upon a new term here and there, such as the "somnifacient action of chloral." Quinine as a substance that decreases the functional activity of all forms of protoplasm is dwelt on, and so is its use in malaria, the importance of its therapeutical application and its exhibition in large doses a few hours before the division of the parasite in the blood. The prolonged use of such "headache powders" as consist of acetanilid is commented on as the habit may give rise to chronic poisoning. Part II. deals with ferments, secretions, and extracts of animal organs, and includes the digestive ferments, bile, adrenalin, and iodothyrin, animal extracts, and artificial foods, but the last of these is dealt with very lightly. The third part treats of drugs the local action of which is most in evidence, such as skin irritants, urinary antiseptics, vegetable purgatives, bitters and astringents, and anthelmintics, and, last, mechanical agents which are used either for their physical effects in the preparation of active drugs or other purpose—e.g., gums, oils and fat, collodion, &c. The last part deals with drugs of inorganic origin, oxygen, acids, alkalies, neutral salts, non-metallic elements, and finally with metallic compounds. The book gives an excellent and precise account of the chief and most useful drugs used in medicine.

The Food Inspector's Handbook. By Francis Vacher, Medical Officer of Health of Cheshire. Fifth edition, thoroughly revised and greatly enlarged. London: The Sanitary Publishing Company, Limited. 1909. Pp. 268. Price 7*s.* 6*d.* net.—We have expressed our appreciation of this useful little work in our references to the earlier editions; and now that in the present (the fifth) edition the section on meat has practically been rewritten in accordance with recent legislative regulations on the subject, and fresh matter also dealing with statutory powers in regard to the adulteration of food has been added, the handbook forms an excellent practical guide for medical officers, meat inspectors, and indeed all sanitarians at the present time. The illustrations are an excellent feature of the book, 27 new drawings having been specially prepared for this edition by Mr. R. E. Holding, who has given great care to detail, and his representations of various pathological conditions are decidedly [illegible]stic. The sections of the book relating to fruit and [illegible]able foods, while including some instructive paragraphs [illegible]gard to the characteristics, preparations, and appear[illegible]e of these foods when sound, are somewhat brief. The book does not pretend to be a work for the analyst, and so, while the subjects of the composition and adulteration of foods are briefly discussed, the methods employed for the detection of adulteration are omitted. The book is well worth possessing by all those concerned in the practical administration of laws designed to insure the purity and soundness of all classes of human food.

1. *Food Reform.* 2. *Hints Towards Diet Reform.* The National Food Reform Association. 1909. Price 1*d.* and 2*d.* respectively.—We have received the two little books above mentioned with a request from the secretary of the association for their notice. No. 1, which is by the Hon. Neville Lytton, urges the need of food reform, and points out how much of our diet nowadays consists of tinned meat and "artificially bleached bread," a subject to which we have referred recently at some length. The great fault of bread nowadays is that it consists mainly of starch, for not only is the flour so prepared in the rolling mill that nearly everything but the starch is removed, but it is stated that a custom exists of "setting the sponge" with water which has been allowed to run through potato pulp. The second book consists of simple recipes for non-meat dishes. They are good enough, but a vegetarian diet does not suit everyone in this climate, and it is no good pretending that it does. Certain persons may find that their health is better if they do not eat meat, and for such persons a non-meat diet is to be recommended. But food reform is a much wider subject than simply the absence from the dietary of flesh food. Two of the greatest desiderata of diet are pure milk and honest bread. If the National Food Reform Association would set itself to secure that these two articles of diet could be obtained everywhere it would be doing a useful work.

Extraction of Teeth. By Frank Coleman, M.R.C.S. Eng., L.D.S. London: H. K. Lewis. 1908. Pp. 158. Price 3*s.* net.—The removal of teeth, although seemingly an easy operation, is, nevertheless, one which to perform neatly and without undue discomfort to the patient requires a thorough knowledge not only of the anatomy of the parts involved but also of the technique of the operation. In this good little work the author has provided a clear and exhaustive account of the operation, and we can cordially recommend the book to those medical practitioners who are called upon occasionally to perform this operation for their patients without being specialists in dentistry.

JOURNALS AND MAGAZINES.

Hospital Gazettes.—Amongst recent contributions to the school journals we have noticed the following. In *Guy's Hospital Gazette* (March 6th) is a paper entitled An Experimental Feeding Trial in Relation to Epidemic Enteritis, by Mr. E. P. Minnett, who after studying 38 infants for 19 weeks concluded that dried milk prepared with boiling water is deserving of further trial in the summer months amongst the poorer classes, as by proper preparation it affords a nearly sterile food which may well prevent a good deal of epidemic enteritis.—In the *London Hospital Gazette* (March) is an interesting note on Some Historical Associations of "the District," illustrated by a map of the Whitechapel, Mile End, and Docks locality in 1794.—The *Middlesex Hospital Journal* (March) contains an article by Dr. J. Strickland Goodall on Pain: its Nature and its Benefits.—In the *St. Bartholomew's Hospital Journal* (February) the editor called attention to an unfortunate mistake by which the name of Dr. H. J. Ilott of Bromley appeared in the obituary list of the recently published hospital year book, whereas Dr. Ilott is in excellent health and active practice. In the March number of the same journal Dr. A. E. Neligan writes on the Practice of Medicine in Persia, in which, as in the constitutional affairs of that disturbed country, the old is clashing with the new.—The *St. George's Hospital Gazette* (March) is chiefly occupied with local affairs, including "A Chapter in the History of St. George's Hospital," which deals with the Crayle family, notable benefactors of the charity.—In *St. Mary's Hospital Gazette* (March) Mr. S. Maynard Smith discourses upon "The Patient's Point of View"—a point of view which the student is perhaps a little apt to overlook. The author proves himself an observant psychologist.—In *St. Thomas's Hospital Gazette* (February) is an address on Eclampsia and the Other Manifestations of Toxæmia in Pregnancy, by Dr. J. S. Fairbairn.

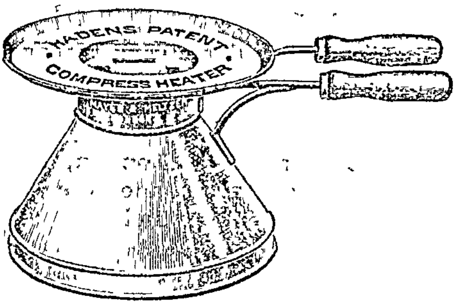
The Contemporary Review for March contains an article by Mr. Jack London which affords an interesting pendant to an annotation recently published in The Lancet on the United States leper settlement in Molokai which has been established to segregate the lepers from the Hawaiian territory. Whereas we dealt with the scientific issue, Mr. London is concerned with the social side of the community, and his particular message is summarised in the vigorous appeal made to him by an engineer patient on the island "For heaven's sake, write us up straight. Put your foot down on all this chamber-of-horrors rot and all the rest of it. We don't like being misrepresented. We've got some feelings. Just tell the world how we really are in here." Mr. London has written them up straight. Without minimising the terrible nature of the affliction which separates these islanders from their homes he shows them to be an active, prosperous, sporting community in which if a man wants to work he can make money, while if he does not feel industrious as a ward of the State he is provided with board, lodging, and clothing, and can idle his time away in a country of extreme natural beauty and with a pleasant climate. Some of the lepers' sports and festivals are described in such terms that later in the course of this interesting article we are not surprised to read: "In the old days, before the discovery of the leprosy bacillus, a small number of men and women, suffering from various and totally different diseases, were adjudged lepers and sent to Molokai. Years afterwards they suffered great consternation when the bacteriologists declared that they were not afflicted with leprosy and never had been. They fought against being sent away from Molokai, and in one way or another, as helpers and nurses, they got jobs from the board of health, and remained." The elaborate precautions taken nowadays to prevent a faulty diagnosis being made are described. These include in every case a bacteriological bioscopy and a subsequent examination by a board of five physicians. Before a patient is sent to Molokai he is kept at a Honolulu receiving station for as long as is necessary to arrange his business affairs, and he is allowed to receive visits from his friends under proper precautions after his segregation. Mr. London's breezy account of this contented lazar settlement is made more pointed by his reference to the mediæval custom of Europe of reading the burial service over a man pronounced to be a leper and regarding him thenceforth as legally dead.

Quarterly Journal of Experimental Physiology. Vol. II., No. 1. 1909. Pp. 108. 6s.—The bulk of this volume is taken up with Dr. J. Macdonald's paper on the Structure and Function of Striated Muscle. Beginning with the undoubtedly unsatisfactory hypotheses explanatory of the facts of muscular contraction—such as the theories of Engelmann (1893), of MacDougall (1897), and the modification of the latter by Bernstein, the author proceeds to indicate the probability that osmotic pressure is a prime factor. The histological evidence shows that actual changes in the distribution of salts have been observed in different phases of muscular contraction. Interesting chapters follow on the theory of muscular contraction and the stability of muscle due to its sarcoplasm, and then are shown the process of contraction and its attendant electrical and chemical consequences. It is the secondary consequences of contraction that determine the occurrence of relaxation. The nature of polarisation, tetanus, and tone lead up to an excellent summary of the author's view. This is a most valuable and suggestive paper. The other papers deal with Recent Work on Protagon, by R. A. Wilson and W. Cramer, with a view to show that this much discussed substance is a proximate principle. There is a short paper on the Pancreatic Secretion, by P. T. Herring and Sutherland Simpson, and one on the Action of Yohimbine, by A. Loewy and Franz Muller.

New Inventions.

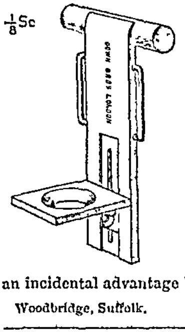
A COMPRESS HEATER.

THIS is a simple but useful invention devised for the purpose of heating poultices, compresses, dressings, and other things of a similar nature for use in medical and surgical treatment As will be seen from the illustration, it consists of a vessel in the shape of a truncated cone, and a pan, perforated in its central part, which fits into and extends beyond the rim of the smaller end of the cone-shaped vessel. The diameter of the pan is about nine inches, the perforated part measuring four inches across. To each of the two parts of the apparatus is affixed a wooden handle which allows of their being moved about without risk of burning the hands of the user. Water is put in the lower part of the apparatus, the compresses or other articles are placed upon the upper tray, and the whole stood over a fire or any form of heating appliance. It will be found that the steam arising from the water heats the compresses almost instantaneously and all risk of scalding the hands is avoided as no wringing is required. Another point worth noting is that in the absence of a properly trained nurse the time of the medical attendant is saved in making detailed explanations and emphasising the risks of scalding when compresses or fomentations are to be prescribed. The appliance should be really useful in hospitals and surgeries in which fomentations are constantly being applied, for, as all former surgical dressers are aware, the preparation of an effectively hot fomentation by means of the old-fashioned "wringer" is attended by considerable inconvenience. For hospital use the heater is made in stout copper, and for less frequent employment it is made in tinned iron at a smaller cost. Messrs. Mayer and Meltzer, 71, Great Portland-street, W., are the manufacturers.



IMPROVED CLAVICLE SPLINT.

I SHOULD like to draw attention to a modification of Mouat-Biggs's clavicle splint which ought, I think, to supply a distinct want. This splint I have found most useful in two or three cases but have been deterred from using it on more than one occasion owing to the difficulty in getting one of the three stock sizes to fit the length of the patient's arm. Messrs. Down Bros have now made a splint with adjustable elbow-piece whereby the length can be altered as required, one splint thus taking the place of three or more fixed splints, an incidental advantage being its increased portability.



Woodbridge, Suffolk. T. CUMING ASKIN, M.D. Dub.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The monthly meeting of the executive committee of this society was held at 429, Strand, London, W.C., on March 19th, Dr. F. de Havilland Hall being in the chair. The record of the business of the society for the early part of this year is satisfactory. The number of sickness claims received has been large but on the whole the sickness experience is rather lighter than for the same period of 1908 The number of new entrants is also quite satisfactory, being well above the average, though rather less than in the corresponding period of last year. As no money is paid by the society as commission and no agents are employed the ever-growing number of new entrants is satisfactory evidence that the benefits offered by the society are appreciated by the profession. Prospectuses and all further particulars can be obtained on application to Mr. F. Addiscott, secretary, 33, Chancery-lane, London, W.C.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1909.

The University of London, the Royal Colleges, and the Degree in Medicine.

We published recently an important report issued by the delegates of the Royal College of Physicians of London and the Royal College of Surgeons of England who had been appointed to draft a scheme under which joint examinations might be established with the University of London with the object of making an M.D. degree reasonably accessible to all London students. That such a consummation may be reached is, we suppose, the desire of the great majority of people interested in the welfare of the University and of the Colleges. It is desired in the first place by the students themselves who intend to enter their profession through the College portals They have watched the development of provincial universities possessing powers to stamp their alumni with the letters which in the public esteem may appear as a badge of particular competence, and see no reason why their own curriculum, which has progressively grown more severe, should not end in a similar hall-mark These letters the Royal Colleges have no power to grant, though the tests which they impose upon those who seek their diplomas are no less searching than those required of aspirants to many medical degrees. In the second place the authorities of the Colleges naturally wish that their men who have passed a degree-worthy examination should obtain a degree on fair terms. Thirdly, this view is shared by a considerable section of the medical faculty of the University of London, who are grievously disappointed at the proportion of London students presenting themselves for the present degrees. It is, as is well known, not shared by many medical graduates who have obtained the degree of medicine of the University of London under the existing stringent terms, and this might very well be expected.

This is an oft-told tale, and the different methods suggested at different times for the wiping out of a blot on our system of medical education are also quite familiar. Everybody knows now that the Colleges cannot remove it for themselves by the simple process of asking for an extended charter. The institution of a one-faculty university is difficult to defend, and the existing universities would oppose the bestowal of degree-conferring powers upon any other class of corporations, however old, however respected, and however learned. The suggestion that a combined degree be given by the University and the Colleges has not only much to recommend it, but no fundamental objection can be preferred to it; it is sanctioned by the University statutes and has now received definite shape by joint action of the Colleges. The report of the delegates, after pointing out that the great majority of London and Cambridge medical graduates take the College diplomas and that at least a half of the College diplomates are also graduates in medicine, calls attention to the examination facilities afforded to the University of London by the Colleges and proceeds to make recommendations. For their full text we must refer to our issue of March 6th, p 706, but we may summarise the main proposals, which are that the "pass" degrees of M.B., B.S., and M.D., should be granted by the University conjointly with or in association with the Colleges to all students who shall have taken at least four years of their curriculum in London; that the Colleges should continue to grant an independent diploma to students not aspiring to the medical degree; and that the University should grant independent "honours" degrees to those seeking higher distinction. These proposals are supported by strong arguments, and the delegates express the wish to meet delegates from the University to consider the matter with a view to presenting a united recommendation to the newly appointed Royal Commission which is to report to the Government upon the present condition of the University.

We are in complete agreement with the desire of the delegates of the Colleges, or rather of the Colleges which have adopted the report of their delegates, that a united and feasible plan may be presented to the Royal Commission, for herein lies the hope of a comparatively swift settlement of grievances which have been an abiding source of difficulty for a generation. If the Royal Commission cannot formulate a satisfactory scheme to render a London medical degree accessible to the normal and hard-working London medical student, then our metropolitan University will stand an acknowledged failure as regards one of its most prominent duties. We were glad to publish a fortnight ago a document which proves the medical faculty of the University to be alive to the gravity of the crisis and desirous of putting its own house in order so as to speak with unwonted authority before the Royal Commission. We refer to Professor E. H. Starling's and Mr. Leonard Hill's scheme to endow a competent board of their faculty with some of the present powers of the academic council of the University. This scheme has been adopted by the medical faculty with further recommendations which we publish on p. 1003 of this issue of The Lancet, and the new Faculty Board will be appointed in July of this year. Whether this board will have all the results which its begetters desire can hardly be told, but we are convinced that the move is in the right direction, and we congratulate the faculty on their confirmation of the views of two of their ablest men. We congratulate them also on the re-election of Professor Starling to the Senate for the coming four years, which will be perhaps more momentous than any that the University of London has yet seen.

Sanitation in the Field.

IN a recent admirable letter to the *Army and Navy Gazette*, over the signature "R.A.M.C.," attention was drawn to an utterance of Lord MIDLETON at a dinner given in his honour at the Royal Army Medical College in February. "Never again," said Lord MIDLETON, "in regard to sanitation, except on the most absolutely and exclusively military points, will the principal medical officer play second fiddle to any combatant officer whatever." All medical officers in the army are conscious how greatly they are indebted to the speaker, who, when Secretary for War as Mr. ST. JOHN BRODRICK, did so much to raise their status and privileges, both professional and military, and we were glad to see prominence given to his weighty words on the subject. The well-informed correspondent of the *Army and Navy Gazette* goes on to contrast the painful process of evolution through which the army medical sanitarian has had to pass before attaining his present desirable position, and quotes, as was inevitable, the very disparaging remarks which Lord WOLSELEY made use of in his "Soldier's Pocket Book" in regard to the sanitary officer with an army, whom he regarded frankly as "a very useless functionary." Army medical officers have long believed that Lord WOLSELEY did not hold them in great esteem—could they, indeed, hold any other view? But "R.A.M.C." proceeds to quote a sentence from the autobiographical recollections and opinions of Sir CHARLES MACGREGOR, in which Lord ROBERTS appears also to have paid little heed—at any rate, in one instance—to the opinion of a medical officer. It was in regard to the site of a camping ground: the site was reported by the medical authority to be objectionable for sanitary reasons; and it is stated that General ROBERTS (as he then was, during the Afghan war) dismissed the medical protest with pungent and discourteous brevity. If the episode as detailed by Sir CHARLES MACGREGOR actually happened in 1880, all we can say is that the attitude towards the military sanitarian thus shown was very different from his lordship's attitude towards the medical authorities of the army during the last 20 years of his service. There has probably never been any Commander-in-Chief in India, or in the field, or at home, who has shown such lively appreciation of the importance of medical and sanitary matters in the service, or been so cordial in his recognition of individual officers who have served under him, as Lord ROBERTS. And we take particular pleasure in recording this fact because certain of the deplorable occurrences in the South African war have been attributed to a neglect on the part of the then Commander-in-Chief to consider sanitary matters in the light of their due importance. This is an unfair view to take and could only be taken by those who are ignorant of the attendant circumstances.

Many years ago the chief medical officer of an army in the field was also the sanitary officer and was attached to the staff of the Commander-in-Chief of the expedition. Lord WOLSELEY objected that the principal medical officer was not, properly speaking, on the staff of the commander, and for some years it was ordered that he should be borne on the staff of the general commanding line of communications. This was found not to work well, and in 1900 it was again laid down that the principal medical officer of a force was to be attached to the staff of the general officer commanding-in-chief. In the existing Medical Regulations (1906) the conditions and arrangements applicable to field service are not detailed. There can be little doubt, however, that the principal medical officer would not be "relegated to the base" or placed in any other position than that in which he is certainly required—namely, on the immediate staff of the general commanding. As regards sanitation in the field, which Lord WOLSELEY in his "Pocket Book" seemed to think of such small moment—a matter merely of "ordinary cleanliness of temporary camps and bivouacs"—the present position is much more satisfactory. On mobilisation of a force a sanitary inspection committee will be formed for service in the field, consisting of a combatant officer as president, a field officer of the Royal Engineers, and a field officer of the Royal Army Medical Corps. This committee will act under the orders of the general commanding-in-chief, and will ascertain that sanitary materials and appliances of all kinds are forthcoming; will coördinate the work of the different military branches, combatant and medical, as well as the sanitary organisation of the country occupied, if any such exists; will initiate schemes of general sanitation; and will visit and inspect stations, and advise local authorities. This small, actively mobile, and responsible committee will deal with sanitary matters in a business-like way, and as it will act immediately under the orders of the general-in-chief, its decisions and recommendations should be promptly and effectively carried out.

At this time of day there is not so much need to dwell on the importance of sanitation for the effectiveness of warlike operations as was the case some years back. A striking instance of the coexistence of the highest military efficiency with at the same time the highest degree of health of the troops, resulting from close attention to sanitation, was recently given by Sir A. KEOGH, Director-General of the Army Medical Service, in an address to the Royal Sanitary Institute. The 7th Dragoon Guards served in Flanders from 1742 to 1747. "During this period it is related of this regiment that it never lost a man by desertion, never had an officer or man tried by general court martial, never had a horse or man taken by the enemy, that it lost but six men by sickness, and had no fewer than 37 of its N.C.O. and men promoted to commissions for distinguished conduct" The colonel, Sir JOHN LIGONIER, had the highest reputation as a fighting soldier and also as a strategist. Moreover, "it is related of him that such was his anxiety for the welfare of his men, that he maintained an additional medical officer in his regiment at his own cost." During these five years in Flanders, when other regiments suffered severely from scurvy, dysentery, and fevers, in this regiment only six men died of disease. As Sir A. KEOGH said, this incident of military history is as brilliant an illustration as can be given of the connexion of sanitation with efficiency in war. But, as the history of medical matters in the army during the latter half of last century shows, it had been forgotten. We may hope, however, in future campaigns, to chronicle similar successes of preventive medicine, now that there is a better chance of the medical voice being heard.

◆

The Prevention of Hæmorrhage in Amputation of the Hip.

AMPUTATION at the hip-joint was not so very long ago one of the most serious and most fatal of all operations. When performed for severe injury to the thigh as a "primary amputation" it almost always ended fatally. In all the 12 cases in which this operation was done in the Crimean war death resulted and in 30 cases after gunshot injury, which were collected by LEGOUEST, all terminated fatally. The results were not so unsatisfactory when the amputation was performed for disease, though here, too, the death-rate was high, for of 42 cases collected by ERICHSEN 18 died. The causes of this enormous mortality were three in number: they were shock, hæmorrhage, and sepsis. Sepsis need no longer trouble the surgeon. From the time of Lord LISTER's epoch-making discovery the risks from sepsis even in operations of the magnitude of amputation of the hip have almost disappeared, provided the surgeon knows, appreciates, and practises the principles of aseptic surgery. It is only in a secondary amputation after severe trauma that the risk of sepsis is at the present day appreciable. The two other dangers, shock and hæmorrhage, still remain. Some recent writers have endeavoured to prove that collapse from hæmorrhage and shock are identical, but in prophylaxis and in treatment it is well to distinguish between them. In both there is a great fall of blood pressure. In shock it is produced reflexly by severe nervous impulses affecting the vaso-motor centre; in hæmorrhage it is produced directly by loss of blood. In amputation of the hip the shock must be great, for the nerves cut through are many and large. It is true that anæsthetics do to a very great extent reduce the shock of so great an ablation of tissue, and the continuous infusion of saline solution during an operation is of great value in maintaining the blood pressure, both when there has been much hæmorrhage and when there has been little. It is, however, in the direction of the prevention of hæmorrhage in amputation at the hip-joint that most work has been done and it is both interesting and profitable to consider the various devices that have been brought forward.

One of the earliest methods was brought into use with the transfixion flap operation. The fingers of an assistant were passed into the wound and compressed the femoral vessels against his thumbs without the flaps. This device has a great effect in controlling the bleeding from the femoral artery and vein, but the hæmorrhage from the branches of the internal iliac artery remains unaffected. The aortic compressor of PANCOAST or of LISTER effectively controls the arterial hæmorrhage but it has no effect on the venous bleeding, for it hardly compresses the inferior vena cava. Moreover, a further great disadvantage is that it is difficult to apply the instrument exactly over the right spot, and if this be not done greater pressure than is needed is liable to be applied, and thus severe damage may result. The aortic tourniquet is almost disused at the present time. Mr. RICHARD DAVY, consulting surgeon to the Westminster Hospital, devised a wooden lever which, introduced by the rectum, was employed to compress the common iliac artery. When rightly applied it was very efficient but it was never adopted to any great extent and it is now almost forgotten. TRENDELENBURG compressed the femoral vessels by passing a strong steel pin behind the tissues in front of the femur and winding an elastic tube round its ends in a figure-of-8. This controls well the hæmorrhage from the femoral vessels, but not the bleeding from the gluteal or the obturator vessels. JORDAN LLOYD'S method consists of the application of a rubber bandage round the hip; it is held in position by means of cords grasped by an assistant; it is very effective, for it exercises almost complete control on the hæmorrhage from all sources. In WYETH'S method a rubber tourniquet is applied round the hip; it is prevented from slipping down by means of two strong steel rods which are passed through the soft tissues on the inner and outer sides of the thigh. This is a very satisfactory method, and it is much more widely used in America than any other device. The loss of blood is minute. In SENN'S bloodless method the head and neck of the femur are first bared through an external excision and a pair of forceps is carried behind the femur to an opening on the inner side of the thigh, and then withdrawn grasping a rubber tube, which is employed to constrict the tissues in front of and behind the bone. The forceps of LYNN THOMAS also deserve mention, where one blade is entered from the outer side behind the femoral vessels and the other blade is placed over the skin, so that the vessels are clamped between the blades.

Many of these procedures are satisfactory and in careful hands will give good results, only a small quantity of blood being lost. Most of them are, however, impracticable if a growth exists very high up in the thigh. The hæmorrhage in an amputation at the hip-joint comes from the common femoral artery and its branches, and from the gluteal, sciatic, and obturator branches of the internal iliac. Any pressure to be effective must be made either on these vessels or on the common iliac artery from which they originally start. Pressure through the abdominal wall is liable to be inexactly applied and it may easily be excessive. In 1894 MCBURNEY of New York had to amputate the thigh of a boy for a large tumour of the right femur reaching quite up to Poupart's ligament, so that it was impossible to employ any constriction method of controlling the hæmorrhage, when it occurred to him that the most efficient method of applying compression to the common iliac vessels would be through an abdominal wound. A small incision was made as if for an appendicectomy, and the vessels were compressed during the amputation, with the result that the loss of blood was very small. Both the iliac artery and vein are compressed and thus loss of both arterial and venous blood is prevented. The additional risk of the abdominal incision is in competent hands almost negligible, especially when the diminution in the loss of blood is taken into account. The method is sound and it should be more widely known. Even in America it is very little used and in this country it is hardly ever employed. We are glad, therefore, to be able to publish in this issue of THE LANCET reports of two cases of growth of the thigh in which it was employed: in one case under the care of Mr. E. W. ROUGHTON and in the other under that of

Mr. T. P. LEGG. In each instance the loss of blood was very small and rapid recovery followed the amputation. The only requirement is an assistant competent to carry out an aseptic laparotomy. It is probable that surgeons in general have not been aware of the existence of this method, otherwise it is certain that it would have received greater recognition than it has up to now. It is more in accord with modern surgical principles to apply a force directly where it is required than to trust blindly to a pressure extending over a wide area, where it may be not merely useless but even actively harmful.

Annotations.

"Ne quid nimis."

THE RECENT POOR-LAW REPORT: THE SPECIAL INVESTIGATION BY DR. J. C. McVAIL.

THE large scope of the inquiry, taken with the limited time at the disposal of the recent Royal Commission on the Poor-laws and Relief of Distress, rendered it expedient for the Commission to adopt numerous and where possible concurrent methods of collecting information. Certain aspects of the matters referred to them appeared to require for their elucidation local investigations in typical districts of a sort which they were unable to undertake personally. From time to time, therefore, they appointed a number of special investigators who furnished them with a series of reports on the various subjects of inquiry entrusted to them, and no doubt these reports will in due time see the light of publicity. To one special investigator, Dr. John C. McVail, county medical officer of Stirlingshire and Dumbartonshire, the responsibility was committed of reporting upon the "methods and results of administering indoor and outdoor Poor-law medical relief in certain unions in England and Wales," a fairly large reference, and Dr. McVail's report, a large blue-book, made its appearance on April 1st. To a certain extent the main recommendations of Dr. McVail's report are well known to those who have studied the Majority and Minority Reports of the Commissioners, for in both reports prominence is given to the views which he has expressed. Indeed, it may almost be said that up to a certain point the Majority Commissioners adopted Dr. McVail's views in respect of the foundation of a Public Assistance bureau, for they state definitely in that section of their report where they review the system of medical assistance to the poor that they are quoting largely from Dr. McVail. The Commissioners, however, do not go so far as Dr. McVail. They do not, for example, add to their provident scheme the inducement of systematic but infrequent medical inspection, while they view with more complacency than Dr. McVail the suitability of the public health authorities of rural England to take over by some scheme of fusion all the duties which now fall under the Poor-law. Dr. McVail's report deals with the medical aspects of pauperism from the preventive side; he is particularly anxious to prevent hereditary pauperism by taking proper charge of the children of widowed mothers and by attending properly to the health of all Poor-law children. His report, which we shall notice shortly with more detail, is a very valuable document, as no doubt the Commissioners, for whom it was written, considered it.

EMANATION AND ELECTRON.

SOME further light on the nature of the radium emanation is thrown by the recent work of Sir William Ramsay, K.C.B., and Mr. R. W. Gray, the results of which were presented to the Chemical Society at its meeting on March 18th last. There are many who are interested in the subject yet who have a vague idea as to what the emanation regarded physically really is. Sir William Ramsay speaks of it as a gas which he and his colleague have been able to prepare in a sta of purity and now they have succeeded in obtaining it in t form of liquid in sufficient quantity for making observatior The liquid is described as colourless, but viewed by its ov illumination even in broad daylight it is visible as a greeni or bluish-green phosphorescent layer, not very luminous, b more luminous than the gaseous layer. When, however, t tube containing it is touched with cotton-wool moisten with liquid air it turns brilliant; the colour changes to bright steel blue and it blazes with light. Continu application of liquid air changes the colour first to whit then to yellow, and finally to orange. Under the microsco it looks like a brilliant arc light. On removing the liqu air the reverse change occurs, the orange light becom yellow, then white, and then blue, and "there seems to some sort of disturbance in the tube, as if crystals of a sol were disintegrating; then appears the faintly phosphoresci liquid, and if the volume be large enough the still mo faintly phosphorescing gas." These changes can be produc again and again and were witnessed by several persons in t laboratory and "there is no doubt that the substance whi is brilliantly luminous is a solid." In his presidenti address, delivered before the Chemical Society at its annu general meeting held on March 25th, Sir William Rams referred to his researches which had indicated that the eman tion had degraded on a minute scale some copper salt in lithium. He had no reason for believing that there was a fallacy in the experiment, for he had taken all the preca tion it was humanly possible to take to exclude the adve titious entrance of lithium. Later his experiments indicat that thorium was capable of engendering carbon dioxide, c in other words, that carbon was one of the degradation pr ducts of thorium. He, however, admitted that many mo experiments would have to be tried before any positive stat ment could be made that certain elements when exposed "concentrated energy" underwent degradation. These ar other investigations he thought gave strength to the hyp thesis that the genuine difference between elements was d to their gain or loss of electrons. To state it simply, an atom of sodium gained or lost electrons, would it be st sodium as we know it, or would it be another elemen In that case it would appear to be reasonable to regard t characteristics and properties of elements as not so much function of atomic weight as of electrons. In other word it is the electron that decides the resolution of the protyl or matter that is null and void into a recognisable entit The "primordial stuff" as the common origin of all element and indicated in Prout's hypothesis nearly a hundred yea ago, thus receives a somewhat remarkable revival. Hyp theses have been buried longer than Prout's hypothes which have since received the dignity of theory because the proved to be a reasonable interpretation of facts in t light of modern research.

A REVIVAL OF POPULARITY IN THE FRENCH MEDICAL SCHOOLS.

FROM the recently published statistics of the numbers c medical students at the commencement of each year in th various French medical schools it appears that whereas th numbers had been steadily falling until 1906, when the reached their lowest point, there was last year a remark able increase of more than 900, part of which was du to foreigners, whose numbers increased from 648 t 819. These have again increased to 961 in Januar of the present year, though the number of Frenchmen ha shown a decrease, being 7320, against 7538 last year. Thes figures, though large, are still considerably below thos reigning 13 or 14 years ago, for in 1895 there were 8916 students altogether, 7779 Frenchmen and 1137 foreigners. On looking through the list it is not surprising to find that by far the largest number of foreign students are Russians, and that these have greatly increased during the last few years, during which there have been troublous times at home. In 1903 there were only 171 Russians, whereas in 1909 there were 592. The contingent sent by Turkey, on the other hand, has fallen from 98 in 1902 to 77 in 1909. The same remark applies to Bulgaria, which only sends 47 this year, as against 101 in 1902. Greece and South America account for more than 20 each, but Great Britain and the United States for only five each. Of course, of all French medical schools Paris is *facile princeps*, the number at present there being over 3500, but Lyons has nearly 1000 and Bordeaux and Montpellier between 600 and 700 each. Few of the foreign students seek the full State diploma which is necessary for the purpose of practising in France. Many, however, take the University degree which does not give any right to practise; 46 such degrees were conferred during 1908. The old diploma of *Officier de Santé* has not been given now for many years, and a foreigner wishing to practise in France must go through the whole course and pass all the examinations which a Frenchman has to pass, no credit being given for any study or examinations already gone through in his own country.

THE UNUSUAL MARCH WEATHER.

THE following table showing the temperature, rainfall, and sunshine for the three weeks, Feb. 28th to March 20th, 1909, is interesting in connexion with the widespread sickness of influenzal type in many parts of the country and especially in London:—

	Mean maximum temperature.	Mean minimum temperature.	Mean temperature.	Difference from average.	Days with rain.	Total fall.	Sunshine.
	°	°	°	°	*	Inches.	Hours.
London, Westminster	41	31	35·7	– 5·5	17	2·0	30
Glasgow	41	32	36·1	– 3·5	9	1·2	41
Leith	41	31	35·8	– 4·8	17	2·0	49†
Dublin	43	33	38·0	– 4·9	14	1·5	77
Manchester, Prestwich	40	29	34·4	– 5·4	9	1·0	36
Liverpool	40	31	35·4	– 6·1	12	1·1	77
Birmingham ...	39	29	33·6	– 6·2	9	2·2	27
North Shields ...	41	30	35·0	– 5·0	17	2·4	?
Yarmouth	39	31	35·0	– 4·4	13	1·4	52
Hastings	39	32	35·7	– 5·6	17	2·5	56
Ventnor	43	33	37·6	– 5·1	16	2·0	77
Plymouth	44	33	38·4	– 4·7	16	3·7	73
Falmouth	43	34	38·5	– 5·2	17	3·6	81
Cardiff	41	30	35·0	– 6·6	16	1·7	60

* A day with at least 0·01 inch.
† These sunshine values are for Edinburgh

A very superficial examination of the above figures for temperature is sufficient to demonstrate the unusual character of the weather for the first three weeks of March, during which sufferers from influenza increased so greatly in number. The places chosen for the above table are all cities or large towns, but they represent equally well the whole kingdom. The coldest week of the three was the first, when the defect of mean temperature over a large portion of the country was between 9° and 12°, while the duration of sunshine was much below the average, and rain, sleet, or snow very frequent and sometimes heavy. During the second week the weather was also much more cloudy than usual and precipitation very common, and the only amelioration during the third week was that over the western half of Great Britain and Ireland there was a good share of sunshine. The wind came from all quarters in turn, but a harsh current from some point of the compass between east and north greatly predominated. The distribution of sunshine exhibits some rather remarkable features. Dublin, Liverpool, and Ventnor recorded exactly 50 more hours than Birmingham and 47 more hours than Westminster, while those two cities were even less sunny than Glasgow and Prestwich. The south coast was relatively sunless for the time of year, and at Hastings, generally ranking among the brightest spots in the kingdom, there were fully 25 hours less sunshine than usual.

THE PEABODY DONATION FUND.

THE governors of the Peabody Donation Fund have recently issued their forty-fourth annual report, relating to 1908. The history of the progress of the work for which this fund was instituted is always full of interest. The princely donations of Mr. Peabody between 1862 and 1873, to promote the better housing of the London poor, amounted to £500,000, and under the careful and judicious management of the governors of the trust the fund had increased to £1,639,435 (or more than three times its original amount) at the end of last year. Since 1873 the net increase to the fund, mainly from rents but including interest and the special bequest last year by the late Mr. Henry Fox of the value of £27,887, has been equal to compound interest on the amount of the donations at £3 per cent. per annum. The capital expenditure on land and buildings during the same period has amounted to £1,529,432; and the net income last year from rents and interest was £40,295, equal to £2·56 per cent. on the capital of the fund, showing a slight decline from the rate of interest in the preceding year. During last year £12,962 was expended in repairs, &c., to the buildings, the whole of which was, as usual, charged to income. At the end of last year the governors had, by means of the fund, provided for the artisan and labouring poor of London 13,308 rooms, besides bathrooms, laundries and lavatories. These rooms comprised 5665 separate dwellings, including 278 cottages of five rooms, 105 tenements of four rooms, 1834 of three rooms, 2548 of two rooms, and 900 of single rooms. The mean population of the Peabody Dwellings has scarcely differed from 20,000 during the past 20 years, the mean population during last year being 19,914, showing a density of 571 per acre, and nine times the mean density in the whole of London. The fact that the population provided with dwellings by the fund has so long remained practically stationary appears to be due to the governors having in recent years devoted the net income of the fund to repaying the balance of the £390,000 borrowed many years ago from the Public Works Loan Commissioners. It appears, however, from the recently issued report that a site has been purchased in Bethnal Green, nearly an acre in area, and that plans and specifications have been approved for the erection thereon of seven blocks of buildings to contain 350 rooms. The vital statistics of the population residing in the Peabody Buildings during 1908 are, as usual, of a generally satisfactory character. The birth-rate was equal to 27·1 per 1000 and was 1·7 above the mean rate in the whole of London. The death-rate, including the deaths of 77 residents removed to hospitals, did not exceed 12·4 per 1000 and was 1·4 below the mean rate in London, and the rate of infant mortality was equal to 116 per 1000, exceeding by 3 per 1000 the mean London rate. This slight excess of infant mortality was quite exceptional, as in the past five years the deaths of infants under one year of age in the Peabody Buildings does not appear to have averaged more than 96 per 1000 births, whereas in the whole of London during the same period it averaged 128 per 1000. All systematic attempts to deal with the housing of the poor are of the first interest to the medical profession, and the latest report of the Peabody Donation Fund makes very satisfactory reading.

A LITHOKELYPHOPÆDION.

THE fact that a fœtus the result of an extra-uterine gestation could be retained for many years in the abdomen was recognised by many of the ancient writers on obstetric medicine. It is said that it was known to Albucasis, the Spanish physician, who died in 1122, although von Siebold makes no mention of this in his account of the works of this writer. Cordæus, in his commentary on the works of Hippocrates published in 1585, records the first authentic case, attributed to Albosius, in which the fœtus was converted into a lithopædion and retained in the abdomen 28 years, and numerous instances of the same kind can be collected from the literature. One of the best known of the lithopædions described by the older writers is the one to be found in the Gynæcia of Israel Spach, 1595, who gives a figure showing the lithopædion *in situ* in the abdomen. In his description of the monster, as he thought it was, he asks, "How comes it that by a reversal of things the tender body of a little babe has limbs near akin to stone?" referring to the classical myth that Deucalion, who in Greek legend corresponded to the Biblical Noah, and his wife Pyrrha after the Flood were commanded by Zeus to throw behind them the bones of their mother—namely, the stones of the hill side—and from those thrown by Deucalion sprang men and from those thrown by Pyrrha sprang women. In 1881 Kuchenmeister recorded his celebrated case in which the calcified fœtus had lain in the abdominal cavity of a woman for 57 years, and collected all the cases to be found in the literature from the year 1582 up to 1880. In 1897 J. G. Clark published a case in which he removed from the abdominal cavity a fœtus weighing 4¾ pounds which had been retained some four years after the date of the rupture of the gestation sac, the patient making a perfect recovery. Most of the tissues of the fœtus had undergone saponification, but there was calcification of an enveloping membrane, probably the amnion, and some calcareous deposits were found in the skin and lungs. This is the largest lithopædion removed by operation in which the patient has recovered. In an interesting *résumé* of Kuchenmeister's paper Clark points out that the case of Varnier and Mangin was the first in which a twin pregnancy existed with the formation of a lithopædion. In 1802 von Weinhardt not only correctly diagnosed a case of extra-uterine pregnancy but operated and removed the calcified fœtus, the woman making a good recovery. In 1821 Bonisch successfully performed the first operation for the removal of a lithopædion by the vagina. In THE LANCET of March 27th, Mr. J. Lionel Stretton has described a case in which he removed during the operation of ventral fixation in a patient, 54 years of age, a globular mass from the left broad ligament. The lump of smooth surface and stony hardness measured 5 inches by 3 inches and on sawing it through was found to contain the well-preserved body of a fœtus of about four and a half months development. This may be an example of what Kuchenmeister termed a lithokelyphos, that is an instance of calcification affecting the membranes of a retained fœtus, the latter as a rule showing only signs of mummification. He limits the term lithopædion to those cases in which the fœtus itself shows signs of calcification beginning, as a rule, in the vernix caseosa and, as in Clark's case, affecting ultimately some of the internal organs as well. Cases in which the calcification affecting the membranes spreads to the skin of the fœtus he terms a lithokelyphopædion. No doubt this is the commonest variety of the so-called "stone babies" of the older writers, since a true lithopædion in which the calcareous deposits are limited to the fœtus is uncommon. It is very likely, indeed, that Mr. Stretton's case is in reality an example of lithokelyphopædion, although no definite information is given as to the presence or absence of calcareous deposits in the skin of the fœtus. It seems clear that in the great majority of these cases the calcification begins in the membranes and affects the body of the fœtus secondarily, and probably in every case the fœtus is the product of an extra-uterine gestation.

WESTERN MEDICAL TRAINING FOR THE CHINESE.

THE awakening of the latent potentialities of the Chinese nation has of late occupied a considerable amount of public attention both in this country and on the Continent, and men capable of appreciating the fire of industrial and perhaps military energies which the present generation is likely to see lit in China are keenly alive to the necessity of securing that the approaching flame shall be confined to the illumination of that ancient empire and shall not threaten Europe with a conflagration. There are no two opinions as to the means of securing this end. Education as opposed to technical instruction affords the only safeguard. The education of the hundreds of millions of people who form the Chinese nation in European morals and ideals must go hand in hand with their instruction in European industrial arts and science if Europe is to watch the kindling of the fire throughout China without apprehension of the ultimate consequences. It would hardly be within our province to speak on a momentous international issue were it not that two important schemes which have been recently laid before the British public to deal with it have both put the medical education of the Chinese in the forefront of their proposals. The reason is not far to seek. Up to the present time Christian missionary enterprise has formed the one link between the interior of China and the civilised world; progress has been slow, but where it has been made at all it has nearly always been due to the establishment of a mission hospital and to the appreciation of the skilful and painstaking treatment which the Chinese countryfolk have received at the hard-working hands of the medical missioners. Small wonder, then, that the prominent citizens of our country who are concerning themselves with the direction of the approaching Chinese renaissance are asking that the torch of learning in the East shall be lit at the lamp of Western medicine. The body which is moving most prominently in the matter is the China Emergency Committee, which held a Mansion House meeting on March 16th under the presidency of the Lord Mayor, who is one of its members, when an appeal was issued for £100,000, of which £40,000 are required for the establishment of medical colleges for the Chinese, to be administered, staffed, and supported by the various existing missionary societies; £40,000 are wanted for training the Chinese in the methods of teaching under Christian influences without imposing religious tests, and £20,000 for supplying Western literature in the vernacular. In an explanatory letter to the *Times* on the morning of that meeting Mr. F. W. Fox, Sir Percy Bunting, and Mr. J. B. Paton, members of the committee, stated that China is in the course of establishing throughout her provinces universities and schools devoted to Western learning, and that the present is from absorption very rarely occur. A few weeks ago we commented on the value of iodine colloid in the treatment of anal sinuses, and Mr. Tatchell's communication forms a further proof that iodine is a very powerful antiseptic, which is hardly used as much as it might be in modern surgery.

TENEMENT HOUSES FOR THE TUBERCULOUS IN NEW YORK.

We are indebted to the *New York Times* for an account of a scheme initiated in that city by Mrs. W. K. Vanderbilt, senior, who desires to make provision for poor families containing a member or members suffering from tuberculous disease, so that the worker may live with his relatives in sanitary surroundings within reach of his work. Slum-dwellings and houses divided into small tenements in ordinary circumstances in New York, no less than with us, are hot-beds in which the disease cannot be arrested in the individual or prevented from spreading to others, and it is felt that charitable treatment in country sanatoriums must be temporary and ill-adapted to the necessities of those whose dependents require the assistance of their labour. For these the ordinary tenement fails to provide a reasonably wholesome dwelling within the confines of the city, although it is recognised to be a profitable investment for its owners, and neither municipal nor private enterprise appears heretofore to have erected anything approaching to what is required in its stead. For this reason the charity of Mrs. Vanderbilt is directed towards the achievement of something more than the mere building at her expense of sanitary flats for 300 or 400 families. Her object is to show, by an experiment on a large scale, that such accommodation may be constructed and managed so as to save human lives and at the same time bring in a reasonable return for the capital involved. Should she succeed in demonstrating this her example will, no doubt, be [illegible] it is quite possible that she may do [illegible] The plans and elevations of her proposed buildings [illegible] not indicate any lavishness of expenditure on ornamental details or on fads extrinsic to the result aimed at. The site selected is suitable without being of an extraordinary character and lies in the middle of the island formed by the intersection of Avenues A and B with Seventy-seventh and Seventy-eighth-streets, having at one end of it a small public square and at the other a school playground, and on its two sides the streets named. The proposed buildings are to be divided into blocks of moderate dimensions, having six floors, including that on the ground level, built round rectangular courtyards at the corners of which are to be staircases open to the air by which the "apartments" or small flats of from two to five rooms are to be approached. Each of these will open directly upon a staircase and will have at least one window facing outwards and another looking into the courtyard, so that it will always be possible to obtain a current of air through the tenement. Moreover, each courtyard is to be entered by two open arched entrances extending upwards from the ground to the level of the ceilings of what we know as the first floor, which should have the effect of making the courtyard an effective air-shaft. The windows of the rooms are to be of good size, those on the outside opening from floor to ceiling and leading out to balconies. Every flat, as it will have at least one outside window, will thus have a balcony, and the tenants are also to enjoy the common use of a roof garden at the top of the block, on which shelters will be provided and other inducements designed to promote out-of-door life as far as possible. There will be no common halls or rooms inside the buildings, these being regarded as an insanitary and noxious feature in the ordinary New York tenement house. The scheme has been matured and its sanitary details formulated under the advice of Dr. Henry L. Shively of the Tuberculous Clinic of the Presbyterian Hospital, and it is hoped that he and other medical men will be able to find for the flats abundant tenants of the class for which they are intended. The enterprise appears to be a sound one, entered upon in a business-like spirit and without ostentation, and if, as is suggested, it can be carried out so as to afford some small annual interest to the generous lady who finds the capital it may lead to the development on a larger scale of sanitary houses for the general benefit of, the working poor of the city. Much, however, will no doubt depend upon the goodwill and intelligence of the families who will inhabit the dwellings. Those actually affected with disease, having, perhaps, had experience in sanatoriums and having actually lived under conditions enforced by medical supervision, will, no doubt, understand how to avail themselves of the opportunities afforded, and it is to be hoped that their families may coöperate with them in giving free access to fresh air and in the maintenance of habits conducive to sanitation. Such habits will probably be new to many of them, and we are given to understand that their adoption will be the subject of advice, but not, or only to a limited extent, of compulsion. The free passage of air outside each tenement by means of open staircases and courtyards (of which, by the way, we have many examples in London) will be a benefit common to all and incidental to their occupancy, but the opening of windows and the use of the balcony and the roof garden will be matters for the exercise of individual discretion. The windows which lead on to the balconies are an important and characteristic feature, and when the commercial aspects of the venture come to be considered by the light of experience it will be interesting to ascertain whether the surface of glass implied is a source of appreciable extra expense, and how it affects the question of warming the rooms of poor people in the more severe periods of a New York winter. No doubt heating combined with free ventilation will be aimed at, but the question of how the warming is to be done is rather lightly touched upon in the account before us when we consider that the tenants are likely to desire in a "cold snap" the maximum of warmth with the least possible personal expenditure upon its attainment, and also that where the conditions of life in a particular set of rooms are according to the will of its occupants, facilities for the admission of fresh air may coexist with its rigorous exclusion.

THE INFLUENCE OF REST IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

In another column we publish a paper by Dr. E. E. Prest on Graduated Rest in the Treatment of Pulmonary Tuberculosis. The writer very properly points out the importance of rest as a therapeutic factor, but in our opinion he rather exaggerates the state of affairs which has hitherto existed when he says that the "rest factor has been in the past ...... far too much obscured." By some observers rest has been too much insisted upon, the patients being allowed to take but very little exercise, and that only of one kind, namely, walking. Dr. Prest, however, makes some valuable comments on the conditions which demand rest and his paper is a useful adjunct to what has been written on "graduated labour." In fact, he makes the somewhat paradoxical, though correct, statement: "Graduated rest may be the same thing as graduated exercise or graduated labour," but insists "there is a difference in the emphasis." The truth of the matter is, that for success in the treatment of pulmonary tuberculosis "graduated rest" and "graduated labour" must go together. The principles of the "graduated labour" treatment were well laid down by Dr. M. S. Paterson, medical superintendent of the Brompton Hospital Sanatorium at Frimley, in a paper read before the Medical Society of London,[1] and he has since shown that if an excess of auto-inoculation has taken place this can be best met by placing the patient under *absolute* rest—that is, by observing the same precautions which are adopted in cases of typhoid fever. Exercise and labour cannot be prescribed unless the temperature is normal, and until such a condition obtains, rest, as Dr. Prest insists, is of prime importance, and if exercise is permitted or indulged in too soon harm will surely follow.

"TEA" VENIENTE DIE.

IT is often asked whether the early morning cup of tea is permissible having regard to the chemical qualities and physiological effects of that beverage, especially under the particular conditions of the human organism after a night's rest. The early morning cup of tea is a source of comfort and refreshment to a good many persons when the mental and physical faculties are in a more or less lethargic state. To them a cup of tea is helpful in giving them, so to speak, a species of courage to face once again the demands and tasks of the day, and that being so it is superfluous for physiology and chemistry to preach that the practice may be beset with troubles connected more or less with the gastric machine. It can hardly be supposed that people who habitually enjoy their early morning tea suffer from any unpleasant symptoms or effects or they would discard the luxury, but, on the other hand, it is conceivable that in some cases mischief in the long run may ensue. It appears to be generally admitted that when tea is harmful at all (and we assume that it is a delicately infused and not long-boiled preparation that is chosen) it is when it is taken without food—that is to say, when the stomach is empty. That is a period when obviously the astringent substances of the tea may act more effectively as irritants to the mucous lining of the stomach and therefore excite a condition of chronic gastric catarrh. Happily, however, it is the custom of most persons to take milk with their tea, which, unless the tea is objectionally strong, neutralises the tannin substances and thus precludes their acting as irritants. The most cogent argument against the early morning cup of tea is that, as in so many cases at all events, the tea is swallowed before the mouth and teeth are cleansed, the septic potentialities accumulated in the mouth overnight are washed into the stomach, and a poisoning process in the system might thus easily be begun. This is not improbably a source of gastric catarrh in some individuals who drink their early morning tea before they leave their bed. The mouth, of course, should be clean before food, and especially before warm drink is indulged in. There is, perhaps, another reason why the institution of the early morning tea is popular, and that not a physiological one. Its preparation implies the stirring betimes of the domestics of the household, but this is a side of the matter which hardly calls for attention in our columns.

GANGRENE OF THE BREAST IN DIABETES.

IN the *Australasian Medical Gazette* for January Dr. H. Swift has reported a rare complication of diabetes—gangrene of the breast. On Oct. 6th, 1906, at 1 A.M. he was called to a woman, aged 64 years, whom he had attended at intervals for diabetes and attacks of angina. She complained of intense pain in the region of the left nipple, which she described as like the sensation of a red-hot iron being bored into the breast. The temperature was 102·6° F. and the pulse was 120 and of fair volume. No definite history of injury could be obtained, but she remembered that a swinging door had struck her on the left side some weeks before. About one and a half inches below and to the outer side of the nipple was a very tender bluish spot of the size of a florin. Morphine was injected and boric fomentations were applied. At 9 A.M. there was a distinct gangrenous area about two and a half inches in diameter with large blebs forming over it. The urine was scanty and of specific gravity 1055, and contained a large quantity of sugar and diacetic acid. Milk diet and half a grain of morphine every four hours were prescribed. The gangrene spread until on the 10th there was a line of demarcation around an area six inches long and four inches wide. The temperature ranged from 100° to 103°. On the 11th a fœtid slough was separating and a new focus of gangrene was extending towards the sternum. The general condition was so serious that the case was regarded as hopeless. However, on the 13th the patient was a little better, and a line of demarcation had formed around the new focus which was about three by two inches. The amount of urine increased and on Nov. 1st it contained no sugar. The two areas coalesced into a large discharging one measuring seven by four inches. All sloughs separated and the wound granulated well and healed with a sound cicatrix. It is remarkable that gangrene should have occurred in a part so near the heart where, unlike the foot, there is no difficulty in the circulation. The disappearance of the sugar from the urine is also noteworthy. It has been observed, however, that the supervention in diabetes of some other disease, such as enteric fever, may be followed by disappearance of the sugar from the urine. Possibly the fever which accompanied the gangrene in this case produced a similar result.

AN EPIDEMIC OF 135 CASES OF ACUTE ANTERIOR POLIOMYELITIS OCCURRING IN VICTORIA IN 1908.

DURING April, May, and June of last year an epidemic of anterior poliomyelitis, far exceeding any previously recorded in the Southern Hemisphere, occurred in Victoria, and Dr. H. Douglas Stephens of the Children's Hospital in Melbourne has epitomised its main features in the *Intercolonial Medical Journal of Australasia* for November, 1908. The disease has been spreading widely during the last four years. In 1905 it was epidemic in Queensland, in 1906 in Norway and Sweden, in 1907 in New York, and in Victoria in 1908. In this last there was a preponderance of male children affected. Nearly two-thirds of all cases occurred in the first three years of life. The disease selected the autumn months (March to June) as the period of greatest incidence, and the majority of cases occurred in children living in the most densely populated suburbs round Melbourne. Dr. Stephens believes that the disease is contagious in a mild degree, and from his observations made during the epidemic he finds the incubation period to be somewhere between three and 16 days, while the invasion stage varies from zero to a week, most commonly from 24 to 72 hours. In seven cases out of 26 recent cases in which lumbar puncture was obtained, cultures of cocci in pairs and tetrads were successfully grown from the cerebro-spinal fluid. These gave a pale lemon-yellow growth, but injection into rabbits and guinea-pigs caused no pus production. Direct examination of the centrifugalised fluid in smears in five cases revealed the presence of poorly staining cocci, extra-cellular, and generally as diplococci, analogous to those obtained by Geirswold in the Norwegian epidemics. Dr. Stephens found in nearly every case a definite history of premonitory febrile illness, and he remarked that in many instances slight cough preceded the onset of the disease. An examination of the pathological material which he has been able to obtain to some extent corroborates the view of Harbitz and Scheeb that the condition begins by a patchy lepto-meningitis on the anterior aspect of the cord, and that the inflammatory process spreads inwards to the highly vascular grey matter. Out of 135 cases six deaths were recorded, a mortality of approximately 4½ per cent.

[1] THE LANCET, Jan. 25th, 1908, p 216.

THE EDITORSHIP OF THE LANCET.

DR. SQUIRE SPRIGGE, who has been chief of the editorial staff of THE LANCET for 15 years, has been formally appointed Editor.

IN connexion with the Fifth Centenary of St. Andrews University, the "Mater Studiorum" of Scotland, to be celebrated some 18 months hence, a prize of 100 guineas has been offered by Dr. J. P. Steele of Florence for the best essay on "Scotland's Debt of Gratitude to her Parish Schools, her Grammar Schools, and her Universities," the competition to be open to graduates of the four Scottish seats of learning and the conditions to be announced *quam primum*. One of these conditions requires the essay to occupy not more than one hour on being read aloud. The subject is one of interest to all the liberal professions—particularly to the medical, in which the Scottish record holds a place of honour quite disproportioned to her population and her financial resources.

A PRESENTATION of his portait was made to Sir William H. Allchin on March 31st in the board room at the Westminster Hospital. A large number of friends and old pupils have used this opportunity of signifying their high regard for Sir William Allchin.

WE regret to announce the death of Dr. Arthur Gamgee, F.R.S., the well-known physician and physiological chemist, which occurred in Paris on March 29th after a very short [illegible]

THE DEATH REGISTRATION AND BURIALS BILL.

ON the first of the past month a Bill to amend the law relating to the registration of deaths and to the regulation of burials was presented to the House of Commons by Mr. George Greenwood, with the support of the Right Hon. Sir Walter Foster, M.D., Dr. V. H. Rutherford, Dr. J. G. Shipman, and others.[1]

From an explanatory memorandum we learn that the object of the Bill is to give effect to the principal recommendations put forth by the Select Committee on Death Certification which sat in 1893 under the chairmanship of Sir Walter Foster. That Committee reported that it was "much impressed with the serious possibilities implied in a system which permits death and burial to take place without the production of satisfactory medical evidence of the cause of death. It is a most important duty of society to guard its members against foul play, and it appears to your Committee that, as far as may be, it should be made impossible for any person to disappear from his place in the community without any satisfactory evidence being obtained of the cause of his disappearance. Your Committee, fortified with the weighty opinions of the witnesses who have appeared before them, have arrived at the conclusion that uncertified deaths should, as a class, cease to exist, and that means should be devised whereby a medical certificate should be obtained in every case not certified by a registered medical practitioner in attendance."

This Bill contains, but not always in a fortunate form, several provisions for the improvement of the registration of deaths which, with suitable modifications, we should gladly see placed on the Statute Book, but although based on the recommendations of the Select Committee referred to, the Bill betrays a certain lack of familiarity on the part of the draftsman with the present system of death registration and with what is required for its amendment, having regard to what is either practicable or desirable under existing conditions.

The first clause of the Bill prohibits the registration of any death except under one of the following safeguards—either (1) the proper certification of the cause of death by the regular medical attendant; (2) a coroner's certificate after inquest; or (3) a certificate of verification by the "public certifier of deaths," for the compulsory appointment of which officer in each registration sub-district provision is made in the Bill. In event of the death of a person attended in his last illness by a registered medical practitioner the medical attendant is required to furnish the registrar with a certificate of the fact, as well as of the cause of death. And here it must be noted that under this Bill the present custom of intrusting the medical certificate to the relatives of the deceased for presentation to the registrar is departed from. The certificate is to be sent direct to the registrar, with the intention, presumably, of rendering it a State document, the property either of the Crown or of some public authority to be appointed for the purpose. That this is the intention of the framers of the Bill is clear from Section 3, which provides for the payment of a definite fee for his certificate to the medical practitioner in attendance, whose responsibilities with respect to the case will as a consequence be considerably increased. Under the Bill he will be required to testify not only to the cause but to the actual occurrence of death in each case, and his certificate will not be accepted unless it bears evidence that the practitioner has attended his patient on at least two occasions, one of which must have been within eight days of the death.

A subsequent section of the Bill provides for cases in which no medical practitioner has been in attendance on a deceased person. In the event of the registrar being in doubt as to whether such person has been attended in his last illness by a registered medical man; or in case of his not having received a proper medical certificate within the time limited by the Act; or, again, in case the registrar is dissatisfied with the medical certificate, he is required to communicate with the public medical certifier of deaths, whose duty it thereupon becomes to inspect the body and to furnish the registrar or the coroner, as the case may be, with the necessary "verification certificate."

In the case of a person the cause of whose death is uncertain, or is believed to be due to violence or to other than "natural causes," the medical attendant is required, instead of certifying the death in the usual way, to inform the coroner and also to notify the registrar of his having so done. On receiving this information, and before holding an inquest, the coroner is required to communicate with the public certifier of deaths, who must attend the inquest, and, if satisfied of the fact of death, must furnish the coroner with a verification certificate which will be forwarded by that officer to the registrar, together with his own certificate, for registration in the ordinary course.

Concerning the question of "stillbirths," the compulsory registration of which was strongly recommended in the report of Sir Walter Foster's committee, the only reference contained in the present Bill is to the following effect:—

> For the purpose of the provisions of the Births and Deaths Registration Acts, 1836 to 1901, and of this Act, relating to the registration of deaths and to burials, any stillborn child which has issued forth from its mother after the expiration of the twenty-eighth week of pregnancy shall be deemed to have been born alive and to have died after birth, and not to be a stillborn child, and these provisions shall apply accordingly.

For the appointment of public certifiers of deaths provision is made in the Bill, the only condition of appointment being that the officer should be a registered medical practitioner, and that he should be appointed by the local board of guardians, presumably with the consent of the central authority as regards duties, remuneration, and dismissal from office. It seems strange that almost synchronously with the publication of the recommendations of the Poor-law Commissioners for the universal supersession of Poor-law guardians as the local authorities for purposes of "public assistance" a Bill should be presented to Parliament suggesting an enormous increase in the functions and responsibilities of these much-abused functionaries, whom the framers of the present Bill would apparently desire to invest with a new lease of life.

---

[1] See THE LANCET, March 13th, 1909, p. 806.

We have already intimated that, in our judgment, this Bill is badly drawn. Indeed, we can hardly believe that, abounding as it does with manifestly impracticable requirements, it can have obtained in its present stage the approval of the registration authorities at Somerset House. In particular, we note that the time for complete registration of a death is so greatly extended by the Bill that the burial of a body would frequently be unduly delayed. In addition to which the preliminaries to registration appear to be far too complicated for execution by the average type of registrar, whilst the duties imposed on the relatives of the deceased, naturally depressed by bereavement, are unnecessarily vexatious if not impossible of fulfilment Again, in a measure the avowed object of which is to provide for the safety of the community in this respect, we should have thought that definite arrangements would have been included for the registration of stillborn children. But, with the exception of the indirect reference to the subject of stillbirths previously alluded to, the Bill is silent on the point.

Having said so much by way of unfavourable criticism of Mr. Greenwood's Bill, we gladly accord our approval to two of its chief recommendations, both of which seem to us just and reasonable, but which, we fear, will hardly escape opposition by certain economists of the House of Commons. The first recommendation provides for the appointment of a public certifier of death in each district of England; the other, for the payment of medical attendants for their certificates and for the greatly increased responsibilities they would incur in the event of legislation on the proposed lines. We think that in the present temper of the House either of these provisions would suffice to wreck this or any other measure of the kind unless strongly supported by the Government It is certain that, on the one hand, the cost of maintaining a corps of "public medical certifiers" would undoubtedly be considerable, but, on the otherhand, by this means alone can the hardly less cost of holding unnecessary inquests as at present be saved to the community. That our national system of registration, which was established in 1837, should now need amendment will occasion no surprise. But before venturing on any piecemeal tinkering with a system under which enormous improvements have been effected in the course of the last 70 years, it is essential that the whole system of registration of births and deaths should be reviewed, with the advice of persons familiar with the merits of the existing machinery as well as its defects. It would appear almost inevitable that the Acts themselves would need practical reconstruction so as, *inter alia*, to provide for the registration of stillbirths and for the acquirement of fuller data respecting both mortality and natality, in order that amongst other important questions the relation of a declining birth-rate and a stationary infantile mortality may be traced to the physical and social conditions of the people.

261

THE REPORT OF THE AMBULANCE COMMITTEE.

In December, 1906, Sir Kenelm Digby, G.C.B., K.C., the Earl of Stamford, and Sir William Collins were appointed by the Home Secretary to form a committee "to inquire as to the provision made for dealing with cases of accident and sudden illness occurring in streets and public places within the metropolis, and to report whether any, and if so what, improvements in ambulance provision are necessary or desirable, and how they could be best effected with due [illegible] led [illegible] the [illegible] maintain or to contribute to the establishment and maintenance of an ambulance service for street accidents in London The House of Commons committee passed these clauses, but the House of Lords committee, though satisfied with the medical evidence as to the need of a good ambulance service, struck them out on the grounds that the financial aspects of the Council's scheme were not made clear in a manner satisfactory to the committee. It was stated, moreover, by Lord Camperdown, the chairman of the committee, in the debate which took place on the third reading of the Bill in the House of Lords that the Home Office was opposed to the Council's scheme. A conference at which the Council, the Home Office, and the police should be represented was then proposed, but the outcome of the discussion seems to have been the appointment of the committee which has now issued its report. This appears two and a half years after the rejection of the Council's clauses in Parliament and eight years after an inquiry by the Council the result of which those clauses embodied, so that it cannot be denied that regrettable delay has taken place, to which the attention of Parliament may usefully be called.

The report in which the committee appointed by Mr. Gladstone explains its views is an interesting but inconclusive document, for unfortunately the committee is not unanimous as to the important question of the selection of a central body to which the duty of organising the ambulance service of London should be assigned. The report, or rather the portion of it for which Sir Kenelm Digby and Lord Stamford must be regarded as responsible, would enlarge the scope of the duties of the Metropolitan Asylums Board so as to include in them the provision of ambulances for accidents and cases of non-infectious illness demanding them, and the working of them with the aid and coöperation of the police. It will be seen that at the inception of its task the committee was not assisted by the terms of its reference, which we cannot help thinking must have been drawn up without due consideration. Strictly speaking, it was limited to the consideration of the ambulance service to be provided for "street cases" (a convenient term adopted by the committee) in the metropolis. Accidents and illnesses occurring in streets and public places obviously do not include those which take place on private premises, such as factories, docks, and railway stations, and the provision of an ambulance service which would omit the care of these would be absurd. The metropolis is presumably definable as the County of London, but the hospitals to which ambulances transport the sick and injured do not draw their patients from so limited an area, and the scope of the inquiry necessarily included the consideration of the services of the metropolitan police in connexion with the transport of "street cases," services which are not denied when cause for them arises on private property. Now the metropolitan police exercise their duties over an area six times as large as that ruled by the London County Council and over which, moreover, a rate is levied for the maintenance of this important body. Questions, therefore, as to the training and employment of the police with a view to their rendering first aid and assisting in the conveyance of injured persons to hospitals could not be discussed either in their practical or financial aspects without reference to conditions outside the "metropolis." The fact that the use of an ambulance is not likely to be confined to street cases has been referred to, but besides these and accidents on private premises there is the demand for means of transport which arises when the poor patient lying ill at home has to be taken to a hospital. Is he to be left for his relatives to convey him in a cab, or cart, or barrow, all of which have been found by the committee to be the inadequate and sometimes injurious vehicles in general use when emergencies arise? However, the committee has interpreted its duties in a liberal spirit, and, while recognising the limits imposed by the authority appointing it, has made inquiries and suggestions which go beyond them. Its difficulties, however, have not ended there, for it has had considerable divergence of opinion among witnesses to deal with, notably upon a point of great importance in the organisation of an ambulance service—namely, the nature and extent of the service to be rendered by those accompanying the vehicle in order to assist in bringing the case to the hospital.

When we come to consider in detail the topics discussed by the committee we observe that it found in existence the following services: that of the Metropolitan Asylums Board, which without legal sanction deals to some extent with non-infectious cases, and by arrangement with the Commissoner

Dr. Robert Heilig Library
S. M. S. Medical College
V/L220

of Police removes necessitous patients from their homes to hospitals but intervenes rarely in "street cases"; that of the St. John Ambulance Association, which places wheeled litters and other appliances at the disposal of the police and public at 35 stations; 399 litters under control of the police, of which 49 are the survivors of those given by the late Mr. H. L. Bischoffsheim; horsed ambulances belonging to boards of guardians and used almost exclusively for their purposes; and various private and other ambulances and litters owned by dock companies and similar bodies with a view to their own needs. In the City of London it found a recently instituted (i.e., in May, 1907) system of an electric motor ambulance, to which others are to be added, capable of being summoned by means of any of 35 electric street call-boxes, much as a fire-engine is obtained when required, the existing ambulance conveying persons in the western half of the City to St. Bartholomew's Hospital, where it is stationed. This City system constitutes the only publicly organised example of the use of the "rapid ambulance" in London, but the practices prevailing in use in other great cities of England, in Berlin, Paris, New York, and Boston have been studied by the committee, the "rapid ambulance" being the vehicle drawn by horses or propelled mechanically as distinguished from the stretcher or wheeled litter. In addition to such special vehicles as those named the committee finds that the use of cabs, carts, barrows, and other unsuitable methods of conveyance in London is too frequent, that patients suffer through it, and also that it is often due in street cases to impatience, the crowd or the injured person urging the policeman who has the case in hand to "commandeer" the first vehicle obtainable. With reference to the nature of the apparatus for the removal of the street case to the hospital the committee is of the opinion that, given an effective method of summoning it, the rapid ambulance is preferable to the wheeled litter, having regard to the rapidity of its arrival where the patient lies, and of its transportation of him to the hospital. The advantages of its use are increased also by the fact that it admits of skilled assistance and necessary appliances being brought to the patient, to whom assistance, not possible with the wheeled litter, can be rendered during transit.

The nature of the views put forward by witnesses as to the extent of the treatment which should be accorded to the street case may be summarised by saying that some would "bring the hospital to the patient," others being content to convey him with as much speed and with as little preparation as may be consistent with his safety to the hospital. The majority of the views adduced were to the latter effect, including such important opinions as those of Mr. Thomas Bryant and Mr. Henry Morris. The former of these supported his opinion by citing the experience of the Japanese in their late war when no aid but what was immediately necessary was rendered either where the wounded were found or at the field hospitals, but all cases, after the wound had been shut up and covered and bleeding stopped, were taken at once to the base hospitals, this course being pursued with success which was "perfectly astounding." Both the two gentlemen named regarded the sending of a qualified medical man or senior student with the ambulance so as to diagnose or treat the case before removal or *en route* as impracticable and unnecessary, and with this view the committee expresses its concurrence, while pronouncing in favour of the provision of rapid ambulances and proceeding to discuss how they should be provided and organised.

As to the authority which should control the ambulance service the committee had before it the opinion of Mr. Morris that it should be a "street ambulance department of the police," his view being that organised by this central authority the rapid ambulance should reach its destination, bringing a specially trained member of the force who should receive the patient from the policeman on the spot and convey him to the hospital. The committee refers also to the need, dwelt upon in the evidence of Sir William Church, for an ambulance service which would include the transport of poor patients lying ill in their homes to hospitals, and considers that the demand for such a service is established, but that it would add too much to the existing duties of the police primarily connected with the prevention of crime. It finds, however, the Metropolitan Asylums Board already providing means of transit for non-infectior [illegible] these are outside its legitimate sphere, and [illegible] "rapid ambulance" stations established for this purpose. In these circumstances the committee formulates recommendations which may be summarised as follows:—

1. That there should be a tentative and experimental introduction of rapid ambulances so organised as to be capable of dealing with cases other than street cases.

[illegible] .uthorised by Act [illegible] a service of non- [illegible] with the Metropolitan police for this purpose, special provision being made with regard to portions of the Metropolitan police district lying outside the area under the Metropolitan Asylums Board.

3. That the attendant to accompany the rapid ambulance should be a police officer specially qualified, and the committee consider that the difficulty arising out of the fact that the policeman in whatever capacity he is employed always remains under the authority of the Chief Commissioner is not insurmountable. They suggest that, as at Manchester, when the person to be removed is a female the ambulance might obtain a matron from the police station, at which, according to one suggestion made, it would call, in order to pick up a reserve police officer to accompany it. It may be mentioned that considerable importance was apparently attached in evidence before the committee to the provision [illegible]) and extension of the private [illegible] of the Metropolitan Asylums [illegible] r communication between the [illegible] the ambulance station the use [illegible] loes not advise, owing to the [illegible] scale of the special call-box [illegible] commends a suggestion that such call-boxes should be placed in some of the busiest thoroughfares and at the most awkward crossings.

[illegible] of the police in the rendering of "first [illegible] ut capable of improvement, and that their [illegible] xercise of their discretion in summoning [illegible] to any new system introduced.

In this connexion we note the following phrase in Paragraph 118 of the report:—

> In view of the recommendations which we are making we think that the summons of the local doctor in cases of street accidents will be seldom required.

We should have thought that in the event of an apparently serious accident happening, as must sometimes occur, close to the spot where a qualified practitioner is to be found, his services might usefully be requisitioned and that provision might be made for his remuneration in such circumstances. In cases in which the rapid ambulance is about to arrive within a few minutes it would clearly not be desirable to send in search of a medical practitioner who, if found, would be likely to be too late to be of use, but to regard him as non-existent when he is close at hand is another matter.

We now proceed to refer briefly to the memorandum appended to the report by Sir William Collins, who, it must be remembered, although in the minority as to the views which he thus expresses, constitutes "one third" of a committee composed of three members only, and a "third," moreover, pre-eminently endowed with experience relating to (1) the medical and surgical aspects of the questions propounded, and (2) municipal matters. He tells us in his memorandum that he signs the report because he is convinced of the need for action, saying, "As to the urgent necessity for reform the report in no way overstates the case. It establishes the fact that notwithstanding the police policy of extending the provision of wheel-litters, especially in recent years, 60 per cent. of all cases of injured or sick persons conveyed to hospitals in London are brought otherwise than by ambulance or litter. The figures show that in more than one-fourth of such cases definite fault is found with the mode of conveyance, that even in serious cases more than one-third of the sufferers are conveyed by means likely to be prejudicial, that the unsuitable cab is still largely requisitioned, and that actual harm is in 1 out of 3 of the more serious cases attributed to its use." He points out also that except in the City there is no special provision made for summoning even the wheeled litter, and that the use of the telephone for such purpose has not been considered necessary. We may here call attention to the fact that although mechanically propelled vehicles have been with us for some years, and telephones also, it is only recently that a rapid extension of the use of both has taken place, so that the advantages and practicable nature of the combination of the two are now so obvious that they cannot be ignored.

Sir William Collins reviews the circumstances in which the London County Council's proposal to establish an ambulance service was rejected in the House of Lords in 1906, and is of opinion that although it is not possible now any more than then to estimate the ultimate cost of an adequate service of [illegible] for London, such a service should be established [illegible] control of the Council, which has already expressed itself willing to undertake the cost, and, moreover, that it should not be done tentatively, but upon a large scale, by a general introduction of rapid ambulances and not merely their experimental use to supplement wheeled litters. His reasons for preferring the County Council to the Metropolitan Asylums Board as the central authority to control the ambulance service include a doubt as to the desirability of conferring new rating powers upon a non-elective body, which, as he points out, was instituted at a time when no county council was in existence and which was originally constituted as a Poor-law authority. He dwells upon the difficulty suggested by witnesses that however separate the two services of the Board might be kept the public would be prejudiced against these ambulances by fear of infection; he points out that in the necessary establishment of a large number of new ambulance stations the Council would have available sites already acquired by them, but the Board would not. He points out also that the dual authority of Board and police recommended in the report would involve a corresponding duplication of departmental control by the Home Office and the Local Government Board. He would have the ambulances sent out by the Council to deal with street and other cases accompanied by attendants, the servants of the Council, specially trained and instructed in first aid and in handling the sick, who would take over the case from the policeman, the latter being responsible for the summoning of the ambulance only and for the administration of first aid pending its arrival. In conclusion Sir William Collins says: "As to the body to be intrusted with the organisation of what is practically a new service in London, I am of opinion that having set aside the police as the authority the duty should be entrusted to the London County Council, who have sought powers and evolved a scheme for the purpose, rather than to the Metropolitan Asylums Board who have not. Such new municipal duties, involving new rating powers, should in my judgment be a function of the central directly elected municipal authority of London ...... and while anxious that no difference of opinion on the question of the authority should prejudice the early establishment of this sadly needed service, I believe that efficiency and economy would alike be served by procedure upon the lines which I have ventured to indicate." It will be observed that this recommendation is for the establishment of a service within the "metropolis," in accordance with the terms of the reference to the committee, and that it leaves the authorities outside the county of London to coöperate with, or to follow the lead of, the metropolis as may be desired. It is a recommendation which should carry considerable weight, owing to the source from which it comes, and it has many practical and, we may fairly say, obvious advantages to commend it.

The London County Council is the great municipal body to which Londoners are learning to look naturally for the performance of public work in their interests. The relieving of the police of duties so remote from their usual functions as the transportation of injured and sick persons should commend itself to all practical persons, as should the advantages arising from the employment of attendants specially trained for ambulance service and exclusively employed upon it. Altogether, we are of the opinion that Sir William Collins's memorandum deserves and will obtain consideration from the legislature fully equal to that accorded to the views of his two colleagues on the committed upon the points with regard to which he differs from them, and we hope that in any case the legislation which is so desirable may not long be delayed.

UNIVERSITY OF LONDON.

A MEETING of the Faculty of
March 12th, was held at th
March 26th, Dr. SIDNEY H.
Faculty, being in the chair.

The following further recommendations and resolution concerning the suggested
passed:—

The Board shall be constitute
March 1st and not later than
shall remain in office until the constitution of its successor. 28 days

Faculty.

RESOLUTION.

That the Senate be requested to resolve that until further order no action on any of the following subjects be taken by the Senate until they shall have received a report thereon from the Board of the Faculty of Medicine through the appropriate council or councils in accordance with the scheme set out below.—

Subject.	*Appropriate Council*
(a) Recognition of Teachers and Courses of Instruction in Medical Subjects	Academic Council.
(b) Medical Curriculum	Academic Council and External Council.
(c) Medical Examinations, including Appointment of Examiners	Academic Council and External Council.
(d) Admission of Schools in the Faculty of Medicine	Academic Council.
(e) Constitution of the Faculty of Medicine ...	Academic Council.
(f) Organisation of Higher Teaching and Research in Medicine	Academic Council

Professor E. H. STARLING proposed, and Dr. F. H. CHAMPNEYS seconded, the following motion, which was carried:—

That the Faculty Board be appointed in July of this year.

The meeting then dissolved.

MEDICINE AND THE LAW.

An Inquest held without Post-mortem Examination.

AN inquest held recently at Falmouth by the county coroner, Mr. E. L. Carlyon, is the subject of a lengthy report in the *Falmouth Packet*, and the story as told by our contemporary is worthy of comment. The inquiry was into the cause of death of a young man, 20 years of age, apprenticed to a boiler-making firm, who was described by his father as a strong, powerful young man who never had had a day's illness, who never tasted intoxicating liquor, and smoked very little. Two months before his decease he was medically examined before admission to a friendly society and on the day preceding it he seemed well; ate his usual dinner and tea, but went out about 9 P.M., and on his return complained that his forehead felt cold and he vomited repeatedly. His mother gave him some tea and brandy and sent him to bed, after which he was heard retching in his room about midnight, and on his father visiting him at 1.30 A.M. he was found to be dead. Dr. G. E Lanyon who was called in described the condition in which he found the body and gave it as his opinion that the vomiting had caused failure of the heart's action, adding that it was difficult to say why it should have done so, as the deceased was apparently a strong and healthy young man. He added that a possible cause of death might have been the presence of a piece of food in the windpipe, but that the length of time since the deceased had eaten and the absence of any appearance of a struggle negatived this. The father stated that his son had never complained of anything, in reply to a question as to the possibility of his having suffered from a weak heart. The verdict of the jury was to the effect that
failure of the heart's action due to
to see of what use an inquest can
absence of a post-mortem examina-
y necessary to point out that such
t only have shown the condition of
the heart but also might have indicated the cause of the vomiting, for which there was nothing to account except a

---

[1] Sections A and B were passed at the previous meeting (see THE LANCET, March 20th, p. 861).

measles slightly exceeded the numbers in recent weeks. The deaths referred to diseases of the respiratory organs in the eight towns, which had steadily increased in the seven preceding weeks from 131 to 187, declined again to 180 in the week under notice, but exceeded by 47 the number returned in the corresponding week of last year. The causes of 23, or 3·1 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had steadily increased in the four preceding weeks from 24·3 to 29·3 per 1000, declined again to 27·2 in the week ending March 27th. During the first 12 weeks of the first quarter of this year the death-rate in the city averaged 25·7 per 1000, whereas the mean rate during the same period did not exceed 19·8 in London and 18·1 in Edinburgh. The 208 deaths of Dublin residents from all causes during the week under notice showed a decline of 16 from the increasing numbers in recent weeks, and included 10 which were referred to the principal epidemic diseases, against 17 and 13 in the two preceding weeks. These 10 deaths were equal to an annual rate of 1·3 per 1000; the rate from these epidemic diseases in the same week was equal to 2·1 in London, and did not exceed 0·9 in Edinburgh. Of the 10 deaths from these epidemic diseases in Dublin last week, five resulted from measles (corresponding with the number in each of the three preceding weeks), two from whooping-cough, and one each from diphtheria, "fever," and diarrhœa, but not one either from scarlet fever or small-pox. The 208 deaths registered during the week included 32 of infants under one year of age and 73 of persons aged upwards of 60 years, differing but slightly from the numbers in the previous week. Five inquest cases and two deaths from violence were registered last week; and 89, or 42·8 per cent., of the deaths occurred in public institutions. The causes of seven, or 3·4 per cent., of the deaths in Dublin last week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all but one of the 1989 registered deaths were duly certified; while in Edinburgh 5·1 of the causes of death were uncertified.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Fleet-Surgeons: E. C. Lomas, D.S.O., to Haslar Hospital; W. J. Colborne to the *Leviathan;* J. Menary to the *Magnificent;* and H. X. Browne to the *Ramillies*. Staff Surgeons: C. T. Baxter to Haslar Hospital, as anæsthetist and radiographer; J. H. Lightfoot to the *Cochrane;* L. Lindop to the *New Zealand;* and S. T. Reid to the *Antrim*, on recommissioning. Surgeons: C. J. O'Connell to the *Roxburgh;* T. D. Liddle to Haslar Hospital; H. B. Hill to the *Leviathan;* L. C. Hunt to the *Cæsar;* and G. C. Cross to the *Leda*.

Royal Army Medical Corps.

The date of transfer from seconded list of Lieutenant-Colonel James Will is Feb. 28th, 1909, and not as stated in the *Gazette* of March 2nd, 1909. Lieutenant Marcus Graham Dill, from the seconded list, to be Lieutenant (dated March 14th, 1909).

Captain R. H. Bridges, on return from India, has been posted to the Cambridge Hospital at Aldershot for duty. Major J. Thomson, from Woolwich, has been placed on the list for service on the West Coast of Africa.

Indian Medical Service.

The King has approved of the following promotions:—Lieutenant-Colonels to be Colonels: Charles Fancourt Willis (dated Nov. 14th, 1908) and William Alfred Corkery (dated Jan. 1st, 1909). Captains to be Majors (dated Jan. 28th, 1909): Jasper Maxwell Woolley, Clayton Arbuthnot Lane, Thomas Bernard Kelly, William Hamilton Kenrick, Charles Henry Watson, Edgar Francis Eardley Baines, George Orr Fern Sealy, Samuel Anderson, Francis Hope Grant Hutchinson, James Leslie Marjoribanks, Alexander Fenton, and Robert Welland Knox. Lieutenants to be Captains (dated Sept. 1st, 1908): Edgar John Cecil McDonald and William Dundas Wright; (dated Feb. 1st, 1909): Harry William Pierpoint, Khandu Ganpatrao Gharpurey, William David Henderson Stevenson, Henry Patullo Cook, William James Fraser, Desmond Charles Villiers FitzGerald, Robert Siggins Kennedy, Bernard Higham, Charles Aubrey Godson Reginald Henry Lee, Patrick Heffernan, Henry Stewar Hutchison, Robert George Gibbon Croly, Stanley Trefus Crump, William Barbour Alexander Kennedy Cullen, and James MacGregor Skinner.

The King has also approved of the retirement of th following officer: Colonel James McCloghry (dated Jan. 13th 1909).

Territorial Force.

Yeomanry.

King's Colonials: Surgeon-Lieutenant William Savil Henderson, from the King's Colonials Imperial Yeomanry to be Surgeon-Lieutenant, with precedence as in the Imperia Yeomanry (dated April 1st, 1908). Royal Wiltshire (Princ of Wales's Own Royal Regiment): Surgeon-Captain Oliver Maurice to be Surgeon-Major (dated March 5th, 1909).

Infantry.

9th Battalion, The King's (Liverpool Regiment): Th announcement of the transfer and promotion of Surgeon Major John William Ellis, which appeared in the *Londo Gazette* of Oct. 6th, 1908, is cancelled. 4th Battalion, Th Lincolnshire Regiment: Surgeon-Major George M. Lowe granted the honorary rank of Surgeon-Lieutenant-Colon (dated March 31st, 1908).

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: Maj (Honorary Major in the Army) Charles Stonham, C.M.G from the Royal Army Medical Corps (Territorial Force), to Lieutenant-Colonel (dated March 5th, 1909). Henry Robin son to be Lieutenant (dated March 5th, 1909). Alexand Findlater to be Lieutenant (dated March 5th, 1909).

2nd East Anglian Field Ambulance: Dudley Willia Boswell to be Lieutenant (dated Jan. 2nd, 1909).

1st Highland Field Ambulance: Arthur Kellas to Lieutenant (dated Feb. 2nd, 1909).

1st Home Counties Field Ambulance: Bertram Charl Alexander Leeper to be Lieutenant (dated Jan. 1st, 1909).

2nd Northern General Hospital: The appointment Edmond Fauriel Trevelyan to the rank of Lieutenan Colonel bears date July 7th, 1908, and not as stated in th *London Gazette* of Feb. 23rd, 1909.

5th Northern General Hospital: Officer whose service will be available on mobilisation: Captain Robert Stewart t be Major (dated Feb. 24th, 1909).

For attachment to Units other than Medical Units.—Captain Edward L. Paton to be Major (dated Sept. 7th 1908). Octavius Roberts Ennion to be Lieutenant (date Dec. 31st, 1908). Alexander Dingwall Kennedy to be Lieutenant (dated Jan. 27th, 1909).

The colonel and officers of the 3rd South Midland Field Ambulance of the Royal Army Medical Corps entertained the Bristol Unit of the corps at a supper on March 20th. Lieutenant-Colonel A. W. Prichard, replying on behalf of the corps to a toast proposed by Captain F. A. Stephens, stated that the corps had risen to its full strength within a year of its inception, and that it was the first corps in the kingdom to become complete without having a bearer company to start with. The origin of this success was rightly analysed by Captain Stephens who spoke of the patriotism of the city in general and the keenness of the officers of the corps. He also alluded to the kindness of Colonel Woodward and the 4th Battalion of the Gloucestershire Regiment in allowing the corps to share the same headquarters, and said that the unit was fortunate in having so many men with a previous Volunteer training, as well as a number who had served as Regulars.

The Army Council has intimated to general officers commanding that the working of the Territorial Medical Service in last year's training season reflects great credit upon all concerned for its thoroughness in face of the many difficulties inseparable from the early stages of reorganisation.

Deaths in the Services.

Surgeon-Major William Galt Black, A.M.S. (retired), on

March 22nd, aged 85 years. He joined the 11th Foot Regiment (now the Devonshire Regiment) as surgeon-major prior to the Crimean war and served through that campaign. He was present at the battles of Alma, Inkerman, and Sebastopol. He afterwards served in Africa and retired from the service in 1863.

VISIT OF THE PRINCE AND PRINCESS OF WALES TO OSBORNE.

On March 27th the Prince and Princess of Wales paid a visit to Osborne. In the evening Fleet-Surgeon C. J. Mansfield, R.N., amongst other officers, had the honour of dining with the Prince and Princess. During the afternoon of March 28th their Royal Highnesses visited the Osborne House Convalescent Home for Officers.

The *Army and Navy Gazette* in its issue of March 27th says:—"We have already alluded to 14 medical officers on the full-pay list having to be provided for by the abolition of retired officers in recruiting and other billets. We are now informed that six additional full-pay officers, on reduction of [illegible] absence of fever, [illegible] by more retired

TIN IN CANNED FOODS.

To the Editor of THE LANCET.

SIR,—I have just read in THE LANCET of Feb. 6th, p. 411, the notice of the recent work issued by the English Local Government Board (Medical Department, No. 7) on the presence of tin in certain canned foods. The subject of tin and other metals in canned foods has long been a matter of interest in this country, and to show the importance of this problem I may call your attention to the action of the National Canners' Association of the United States in convention at Louisville, Kentucky, during the first week in February. At that convention numerous articles were read on the *contamination of tinned goods*, both with tin and other objectionable metals, and resolutions were adopted looking to the betterment of conditions in this line, especially in the coating of the tin plates. It is not my intention in addressing you, however, to discuss this problem in any technical way, but to say a word in regard to the results of the investigations which are reported in the official document of the Local Government Board No. 7, to which I have just called attention. The authors of this paper have kindly sent me a copy thereof and I have been much interested in the character of the work done, the thorough manner in which the investigators have gone about it, and the careful control of all the conditions of the investigation. The remarks on the methods of detection and estimation of metals in tinned foods are of particular value to analysts everywhere. The study of the action of the acids of fruits, &c., upon the plate is also full of interest, likewi [illegible] tin is of value to all [illegible]

Thi [illegible] I desire to say. The pharmacological experiments conducted by Dr. S. B. Schryver were carried out upon himself and upon dogs. Dr. Schryver describes himself as being in normal health. The last paragraph in the third conclusion of Dr. Schryver's paper is as follows:—

> [illegible] robability of serious [illegible] irritant compounds [illegible] canned foods and is [illegible]

It appears to me that this paragraph might have been well omitted. Assuming as true that Dr. Schryver experienced no ill effects from eating tin and that the dogs were not injured by their diet of tin, it seems unwise to assume that it is practically a harmless substance. It is true without doubt that if a drug be administered in foods which injure healthy persons, it is certain that it is not a suitable substance to be put in foods. But drugs may be put in foods which during a short time do not appreciably injure the health of healthy persons, and yet *that is no reason* why they should be permitted. Dr. Paul Ehrlich lately said in an address before the German Chemical Society: "It *is not* enough simply to inject every new remedy into the bodies of animals; in order to obtain more valuable data on the action of the remedy the animal *must* be *sick or* be *made sick* before the drug is tested upon it." In the light of this testimony Dr. Schryver should not intimate that tin salts are not injurious until he has tried them upon infants, sick people, and convalescents. There are millions of people who eat canned foods besides Dr. Schryver, and of these millions a very large percentage have disordered digestion, are not in good health, and are not in a condition to resist toxic effects of even small quantities of tin.

Medical men, in my opinion, should not make statements which may be used, although they are not intended to be so used, to promote and protect, what Judge Anderson of the Federal Court at Indianapolis recently termed, "immoral practices in food preparation." Judge Anderson in one of the cases which was argued before him, in which benzoic acid had been used in foods, referring to the statements of experts that it was not injurious to health, said that he did not care whether it was injurious to health or not; there was a difference of opinion on this subject and the court would not attempt to decide; but further than this he stated that "the use of benzoate of soda is, as the evidence shows, primarily for promoting the utilisation of low grade, partially decayed, and waste materials, and hence it is used for immoral purposes and should not be permitted." The danger which comes from this conclusion of Dr. Schryver is that in the effort which is now making in this and other countries to secure better packages for canned goods those who use imperfect packages, poor tin, exposed solder, &c., will quote just such opinions as *this as a justification of their acts.* I would *not insinuate for* a moment that Dr. Schryver had any such purpose in view, but experts, and especially medical experts, it appears to me, should be *extremely careful to so guard their expressions as* not to see them used thereafter to protect practices which should be restricted. For my part I can see no possibility of any good ever coming from such a conclusion. Nobody wants *to eat tin salts*, whether they have injured Dr. Schryver or not. Every high grade manufacturer wants to keep them out of his goods and everyone who is a guardian of the public [illegible] this kind and dis- [illegible]

[illegible] t right to express the results of their investigations no one will deny, but if, in the expression of these results, encouragement of the continuance of improper practices may be given it would be a wiser thing on *the part of the investigator to withhold them* from publication. The words of the Apostle are most excellent in this case—"All things are lawful *unto* me, but all things are not expedient" (I Cor. vi. 12).

I am, Sir, yours faithfully,
H. W. WILEY, M.D.

Washington, D C., U S A., March 16th, 1909

PROPOSED LEGISLATION IN REGARD TO THE ADMINISTRATION OF ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Now that the question of legislation to control the administration of anæsthetics is definitely before Parliament (*vide Times*, March 26th) it is important that the whole medical profession should realise and express an opinion upon the first point which will have to be settled—i.e., who *shall and who shall* not administer a general anæsthetic. All thoughtful persons seem to agree that if we are to reduce the number of accidents in connexion with the use of these [illegible] to decide who shall be intrusted [illegible]

medical profession, and the dental profession—to come to some understanding on this specific point.

The recent correspondence in your columns, Sir, has disclosed the unfortunate fact that, at all events amongst members of these two professions, there is considerable [illegible]
differ [illegible]
would [illegible]
tion, [illegible]

provisos, for anyone but a legally qualified medical practitioner to administer *any* general anæsthetic. This we may call, for purposes of description, the larger policy. On the other hand, we have those who would make an exception in the case of registered dental practitioners and would allow them to administer nitrous oxide for dental operations. This we may speak of as the smaller policy. At the present juncture, which is one of far-reaching importance, these two policies are before us and it is our duty carefully to consider which of them should be adopted. We must put aside all personal and class considerations and have as our fixed objective the greatest good of the greatest number. The public expects, and the two interested professions should be prepared to provide, the best possible safeguards against those risks which are inseparable from the employment of all agents administered with the object of producing unconsciousness during surgical operations. I regard it as an idle quibble to argue that because nitrous oxide is the safest general anæsthetic it should become the subject of special legislation. It is an agent which, administered in its pure form, is irrespirable, on the average, for more than one minute. In certain cases—e.g., angina Ludovici, Hodgkin's disease, sub-lingual abscess, tracheal pressure from an enlarged thyroid or other causes—it may be more dangerous than any other anæsthetic. Many years ago, in the operating room of a well-known dentist, I had to perform laryngotomy under pure nitrous oxide in order to restore respiration which, owing to certain abnormal conditions in the upper air-tract of the particular patient, could not otherwise be re-established. Only last year, whilst administering nitrous oxide and oxygen for a dental operation to a patient whose tongue had been removed and whose power of swallowing had thereby become interfered with, respiration ceased owing to the entry of fluid secretions into the larynx, and it was only with the greatest difficulty that I was able, with the efficient assistance of my colleague, to restore respiration. Again, in various pathological conditions of the cardio-vascular system nitrous oxide may, under certain circumstances, be an unsuitable or even a dangerous anæsthetic. Apart, however, from any immediate circulatory risk attached to its use there is a certain amount of evidence that when administered so as to produce a greater or less degree of cyanosis this anæsthetic may impose an undesirable and possibly a permanent strain upon the heart. In his admirable work "Anæsthetics, their Uses and Administration," fourth edition, p. 115, Dr. Dudley W. Buxton says: "The heart seems seldom primarily affected, but if feeble and asthenic it is certainly liable to fail should the respiration be in any way hampered, so that syncope can thus be brought about and may prove fatal." I am not for one moment wishing to act as an alarmist in regard to nitrous oxide. I fully admit it is the safest known general anæsthetic and that when administered *in appropriate cases* and *by appropriate methods* it is practically free from risk to life. But as I am firmly convinced, after many years' experience of dental practice, that in order to secure the greatest safety under this agent it is necessary that the administrator should not only have had ample clinical experience in its administration, but at least that amount of training in general medicine and surgery demanded by the General Medical Council of candidates before their final *medical* examinations, I shall, I fear, never be able to see my way to support the smaller of the two policies now before the profession. What greater argument in favour of the larger policy could there be than the fact referred to by Mr. Morton Smale on March 11th last when presiding at the annual general meeting of the Royal Dental Hospital of London, that over half a million nitrous oxide administrations had been conducted at that institution without a single death? Who conducted this vast number of administrations with such conspicuous success? The reply to this question is that acting in the public interests the Royal Dental Hospital of London has always obtained the services of medical men as anæsthetists. With this object-lesson before us, would it be right to depart from such a well-tried custom? Whilst fully admitting that the general medical and surgical training of the present generation of dentists is perfectly adequate so far as the practice of pure dentistry or dental surgery is concerned, I contend, with no disrespect whatever to anyone, that that training, as specified by the General Medical Council, is inadequate for the protection of the public against the risks of general anæsthetics, including nitrous oxide.

Were it impracticable to supply the public throughout the country with well-trained medical men the case would be totally different. One argument which the supporters of the smaller policy are constantly advancing is that, speaking generally, the average dental practitioner is more competent to administer nitrous oxide than the average medical practitioner. I admit that at the present moment there may be some truth in this contention. It could easily be arranged, however, that before any Act came into force all medical students and all medical practitioners who would under the new *régime* be called upon to administer nitrous oxide for dentists should make themselves thoroughly competent administrators. As I have before stated, there is an immense amount of unutilised clinical material at our dental hospitals and in the dental departments of our general hospitals which could easily be requisitioned for educational purposes, in order to supply the public, by the time that any Act came into force, with medically qualified and fully experienced administrators of nitrous oxide.

Another argument is that the dental profession would suffer by the proposed change. I contend, however, that precisely the opposite would be the case. In the first place, it must be remembered that no proposal has been made to interfere with any vested interests: all registered dentists in practice at the passing of the Act would have the right to administer anæsthetics in the future. Secondly, the constant association of medical men with future dentists in anæsthetic cases would enable the latter to do greater justice to the essentially surgical part of their work, whilst they would certainly not lose in prestige by such an association. Thirdly, the decided blow which would be dealt to unregistered dental practice—for no unregistered dentist could either administer an anæsthetic or have one administered for him—would increase the practice of the registered practitioners. And here let me say a word with regard to the communication forwarded to you, Sir, by the staff of the Incorporated Dental Hospital of Ireland.[1] If their *suggested amendment to Clause I. of the General Anæsthetics* Bill were adopted all registered dentists not *medically* qualified would become entitled to administer anæsthetics not only in dental but in general surgical operations. Surely this is going rather far. That aspirations in this direction are, however, in the air is obvious from a letter in your issue of the same date, the writer of which, a dental practitioner without a medical qualification, administers nitrous oxide for operations by his surgical colleagues. This same correspondent, I regret to note, seems to favour the practice of dentists administering nitrous oxide and then operating, with only an "attendant" present. I have already pointed out that out of the 12 fatalities which have afforded such ample material for criticism in your columns no less than 11 took place under such circumstances. I would repeat that this is one of the strongest arguments in favour of the larger policy. If dentists are to be legally recognised as competent to administer nitrous oxide for dental operations this dangerous single-handed practice will undoubtedly persist. It is to be hoped, therefore, not only for this reason but for the others to which I have referred, that advantage will be taken of the present opportunity to place an essentially medical function in the hands of those who, by their medical training, are most fitted to exercise it. I take it that whatever decision may be arrived at on the point in question by the various medical and dental associations, academic institutions, and societies no legislation will take place without the full and *final sanction of the General Medical Council*, and I sincerely hope that that Council will, when the time arrives, give its unqualified support in the direction I have indicated.

As to the inclusion of local anæsthetics in any legislative measure there is doubtless great difficulty. I quite agree with Dr. Buxton that it would be of advantage to the public if some such restrictions could be enforced, but the insertion of the words he proposes at the particular point he describes in Clause I. of the General Anæsthetics Bill would, I fear, render the meaning of the clause somewhat obscure, and at the same time hardly provide against the particular risk in question—that of injecting cocaine and allied substances. At the same time it might be found possible, after careful consideration, to provide against these risks by some slight addition to the Bill. I am, Sir, yours faithfully,

---

FREDERIC HEWITT.

Queen Anne-street, W., March 30th, 1909.

THE BROMIDE TREATMENT OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—I have read with great interest the excellent address of Dr. James Taylor on Some Points in Treatment of Nervous Diseases published in THE LANCET of March 27th. It contains many practical suggestions on the treatment of some common diseases of the central nervous system which cannot fail to be of use to the general practitioner. I, however, do not quite agree with the author in the prominence which he gives to what is usually described as the bromide treatment of epilepsy, which is probably the commonest of all nervous diseases met with in practice. Dr. Taylor regards bromide as our "sheet anchor" in epilepsy, by which disease I presume he means idiopathic epilepsy. He quite properly points out that such treatment is not unattended with certain dangers—for example, "acne" and "cardiac depression." There is, however, a still greater danger—namely, the production of cerebral depression caused by the chemical action of the drug on the delicate cortical neurons. Such action has been aptly described by Professor Mott as resulting from *chemical restraint* of the nerve cells. It has been asserted that the prolonged administration of bromides is liable to incite changes in the cortical nerve cells indicating some degree of chromatolysis and even complete dissolution. Clinical observers in many of our largest asylums have noted that the continuous bromide treatment of their epileptics, whilst certainly tending to reduce the number of fits, produces in many cases that gravest of all mental diseases, dementia. It is, therefore, not surprising that in some of these institutions bromides are never used in the treatment of epileptics. Recent research points to the etiological factor in epilepsy being dietetic in nature, especially as regards the calcium metabolism of the body. Consequently it is advisable to place these patients on a farinaceous rather than a carbohydrate diet, and clinical observation proves that decided benefit results therefrom. Further, the daily administration of magnesium sulphate (ʒi. doses) is found to have a beneficial effect. It is known that intraspinal injection of a solution of this drug causes par[illegible] it may be [illegible] ing in so[illegible] Other points to be remembered in the treatment are suitable occupation, exercise, and warm baths, which latter are of use when the fits are very frequent. I would therefore arrange the points in treatment in order of their importance thus: (1) Dietetic; (2) occupation and exercise; (3) warm baths; (4) *magnesium sulphate; and* (5) *bromides.*

I am, Sir, yours faithfully,

W. J. MAGUIRE, B.A., M.D. R.U.I., M.R.C.P. Irel.

Belfast, March 29th, 1909.

THE EXTENSION OF THE USEFULNESS OF COTTAGE AND OTHER HOSPITALS: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—It frequently occurs in the experiences of most general practitioners—especially those in outlying country districts—that poor patients are attacked with sudden illness which necessitates prompt surgical interference. Their removal to the nearest hospital over rough and dangerous roads, probably in an unsuitable vehicle, often adds to their sufferings and minimises their chances of recovery. Many a precious moment, and I may say many a valuable life, has been lost by this procedure. But what alternative has the general practitioner to suggest? The slender purse of his patient forbids the summoning of a consulting surgeon and a trained nurse, or if he is able to procure an anæsthetist he possibly feels himself incompetent to perform single handed some rare major operation. I may enlist your sympathies when I say that I reside some 14 miles from the nearest medical man, and when one or two of my experiences have been related the remedy which I suggest will be more readily understood.

During the last 12 months my partner and I have been called upon to perform 11 major operations, and fortunately all but three were able to pay the usual fee. But what about the three? It was as much as their lives were worth to attempt to remove them to a hospital; the rough approach to their moorland homes, the nature and acuteness of their illness, and the absence of an ambulance or suitable vehicle forbade it. One case—a case of ruptured ectopic gestation—occurred at a most outlandish farmhouse with an impossible approach. With operating bags we had to wade through huge snowdrifts over ground where it was quite impossible to take a horse, much less a trap. As the internal hæmorrhage in this case was severe every moment was of importance, and as the nearest hospital was some 28 miles away and the roads were impassable the only thing to do was to operate "at home," and this we did. The patient made a rapid recovery and was well and about in six weeks. On Feb. 13th I was called to see a poor man's wife and acute appendicitis was diagnosed, probably with perforation. The total earnings of her husband were 24*s.* weekly, and in every way she was a suitable case for hospital treatment. Her removal was out of the question, as the peritonitis was rapidly spreading and delay was dangerous; moreover, the distance from hospital was some 22 miles. Fortunately, I was able to obtain an anæsthetist who motored over and brought a trained nurse with him, and with the nurse as my assistant I performed appendectomy, removing a very offensive and gangrenous appendix. The patient is doing well up to the present, but her only chance lay in the operation being performed "on the spot" with as little delay as possible. But the expense is far too heavy for their little income—the taxicab, the anæsthetist, and a trained nurse for at least a fortnight.

To my mind, something ought be done by all public hospitals for those patients with limited means who are not as fortunate as their fellow-sufferers in towns who happen to reside within the "call" of the ambulance. Let me suggest that all public hospitals, especially those which draw their patients from large agricultural districts, should establish a fund to be called "The Out-patient Emergency Fund"; this fund to be expended in providing for an operation in cases of emergency unfit for removal and suitable for hospital treatment. Could not some hospitals arrange that their surgeons should be motored out to such cases as I have described, the expenses to be charged to the fund? The surgeon, if necessary, could take with him the hospital anæsthetist and a "theatre" nurse, or where the surgeon did not require an assistant the general practitioner would give the anæsthetic. The medical men in attendance on these cases ought to be privileged to "wire" to the nearest hospital for assistance, using a code word as may be agreed upon—for example, I should suggest some such message as this, viz.: "—— Hospital, York. OPEF. Appendectomy. Jones, Castlegate, Church Fenton. Dr. Roberts." The code word OPEF. would signify that it was a poor patient entitled to the benefits of the Out-patient Emergency Fund; the second word would give the probable nature of the operation, and the following would give name and address of patient and medical man. The hospital authorities might even go so far as to provide a fortnight or three weeks' surgical dressings, according to the nature of the operation

Of course, it would be necessary to safeguard against the abuse of such a scheme, and to do this effectually the surgeon should have the right to refuse to operate on his arrival if he thought the emergency not sufficiently great or his patient unsuitable for hospital treatment. Looking at it from the hospital's point of view, the expense would not be any greater than if the case was admitted to one of their beds. The cost of the motor hire would probably be equivalent to a patient's three weeks' board in hospital, taking an average. I find it possible to hire a taxicab for a distance of between 20 to 25 miles, to remain an hour or two before returning, at the cost of 2 guineas for the round trip. This would mean that, for example, a case of perforated gastric ulcer could be dealt with by an experienced [illegible] miles [illegible] cost of and two or three [illegible] patient about 3 guineas t[illegible] visiting would be called [illegible] fees of the general practitioner and occasionally (where the fees of the district nurse could not be obtained) the services of the district nurse could not be obtained) the provisos, for anyone but a legally qualified medical practitioner to administer *any* general anæsthetic. This we may call, for purposes of description, the larger policy. On the other hand, we have those who would make an exception in the case of registered dental practitioners and would allow them to administer nitrous oxide for dental operations. This we may speak of as the smaller policy. At the present juncture, which is one of far-reaching importance, these two policies are before us and it is our duty carefully to consider which of them should be adopted. We must put aside all personal and class considerations and have as our fixed objective the greatest good of the greatest number. The public expects, and the two interested professions should be prepared to provide, the best possible safeguards against those risks which are inseparable from the employment of all agents administered with the object of producing unconsciousness during surgical operations. I regard it as an idle quibble to argue that because nitrous oxide is the safest general anæsthetic it should become the subject of special legislation. It is an agent which, administered in its pure form, is irrespirable, on the average, for more than one minute. In certain cases—e.g., angina Ludovici, Hodgkin's disease, sub-lingual abscess, tracheal pressure from an enlarged thyroid or other causes—it may be more dangerous than any other anæsthetic. Many years ago, in the operating room of a well-known dentist, I had to perform laryngotomy under pure nitrous oxide in order to restore respiration which, owing to certain abnormal conditions in the upper air-tract of the particular patient, could not otherwise be re-established. Only last year, whilst administering nitrous oxide and oxygen for a dental operation to a patient whose tongue had been removed and whose power of swallowing had thereby become interfered with, respiration ceased owing to the entry of fluid secretions into the larynx, and it was only with the greatest difficulty that I was able, with the efficient assistance of my colleague, to restore respiration. Again, in various pathological conditions of the cardio-vascular system nitrous oxide may, under certain circumstances, be an unsuitable or even a dangerous anæsthetic. Apart, however, from any immediate circulatory risk attached to its use there is a certain amount of evidence that when administered so as to produce a greater or less degree of cyanosis this anæsthetic may impose an undesirable and possibly a permanent strain upon the heart. In his admirable work "Anæsthetics, their Uses and Administration," fourth edition, p. 115, Dr. Dudley W. Buxton says: "The heart seems seldom primarily affected, but if feeble and asthenic it is certainly liable to fail should the respiration be in any way hampered, so that syncope can thus be brought about and may prove fatal." I am not for one moment wishing to act as an alarmist in regard to nitrous oxide. I fully admit it is the safest known general anæsthetic and that when administered *in appropriate cases* and *by appropriate methods* it is practically free from risk to life. But as I am firmly convinced, after many years' experience of dental practice, that in order to secure the greatest safety under this agent it is necessary [illegible] is administrator should not only hav[illegible] observations on experience in its adminis[illegible]ontal and vertical, and find corresponding differences without any difference in the length of the arm as measured from the axilla. Dr. Hill need not therefore run away from his observations, but as proofs against my contention that the arterial wall when thickened affects the amount of pressure required to obliterate the artery they fall to the ground.

With regard to the second set of observations, I pointed out that Dr. Hill could only get the venous pressure as high as the arterial by his method of investigation, as he stopped any further engorgement on the distal side of the bag on the forearm when he reached the arterial obliteration pressure. This I still maintain to be a quite apparent fallacy in his method. With regard to his criticism of my method, firstly, the wristlet I used was not an "unenclosed bag," but enclosed in the same way as the armlet; secondly, I could repeat Dr. Hill's observations up to the point at which the artery was obliterated with the wristlet applied to the entire circumference of the arm; thirdly, I have found that when the wristlet was applied to a radial artery winding to the back of the wrist I could obliterate it with a pressure of 30 mm. Hg less than was required to obliterate the brachial by the armlet; and fourthly, when applied to a venous trunk the same must be true. *I maintain that my method* measures the venous engorgement pressure, while Dr. Hill's

Were it impracticable to supply the public throughout the country with well-trained medical men the case would be totally different. One argument which the supporters of the smaller policy are constantly advancing is that, speaking generally, the average dental practitioner is more competent to administer nitrous oxide than the average medical practitioner. I admit that at the present moment there may be some truth in this contention. It could easily be arranged, however, that before any Act came into force all medical students and all medical practitioners who would under the new *régime* be called upon to administer nitrous oxide for dentists should make themselves thoroughly competent administrators. As I have before stated, there is an immense amount of unutilised clinical material at our dental hospitals and in the dental departments of our general hospitals which could easily be requisitioned for educational purposes, in order to supply the public, by the time that any Act came into force, with medically qualified and fully experienced administrators of nitrous oxide.

Another argument is that the dental profession would suffer by the proposed change. I contend, however, that precisely the opposite would be the case. In the first place, it must be remembered that no proposal has been made to interfere with any vested interests: all registered dentists in practice at the passing of the Act would have the right to administer anæsthetics in the future. Secondly, the constant association of medical men with future dentists in anæsthetic cases would enable the latter to do greater justice to the essentially surgical part of their work, whilst they would certainly not lose in prestige by such an association. Thirdly, the decided blow which would be dealt to unregistered dental practice—for no unregistered dentist could either administer an anæsthetic or have one administered for him—would increase the practice of the registered practitioners. And here let me say a word with regard to the communication forwarded to you, Sir, by the staff of the Incorporated Dental Hospital of Ireland.[1] If their suggested amendment to Clause I. of the General Anæsthetics Bill were adopted all registered dentists not *medically* qualified would become entitled to administer anæsthetics not only in dental but in general surgical operations. Surely this is going rather far. That aspirations in this direction are, however, in the air is obvious from a letter in your issue of the same date, the writer of which, a dental practitioner without a medical qualification, administers nitrous oxide for operations by his surgical colleagues. This same correspondent, I regret to note, seems to favour the practice of dentists administering nitrous oxide and then operating, with only an "attendant" present. I have already pointed out that out of the 12 fatalities which have afforded such ample material for criticism in your columns no less than 11 took place under such circumstances. I would repeat that this is one of the strongest [illegible]logical cases were "measured simultaneously, with [illegible] armlet on the arm and the other on the leg connected with one manometer, and the observer feeling radial and posterior tibial at the same time." In the 21 high-pressure cases and ten cases of normal or low blood pressure without evidence of arterial disease, of which the results will shortly be published, the leg and arm readings were made successively.

I quite admit that to draw conclusions from one case in which arm and leg readings are made it is essential, as Dr. Hill says, that the readings should be made simultaneously. I believe, however, that in taking the average difference from a large number of cases as I have done any error due to the arm and leg readings not being simultaneous will be eliminated. That this is so is I think sufficiently shown by the fact that in my series of cases of normal or low blood pressure without evidence of arterial disease the average difference between the systolic arm and leg readings is less than two millimetres, and that both this series and that of cases of high blood pressure yielded on the average an identical diastolic arm and leg reading.

Since completing my paper, however, I have made simultaneous arm and leg readings on five high-pressure cases, and in four of these have found the leg readings to be distinctly higher than those on the arm; moreover, in two of the cases the difference was a very marked one. I have in these adopted both the above method recommended by Dr. Hill and another plan. *In this the armlet on the leg is* connected with one manometer, that on the arm with another.

One observer reads the arm manometer and feels the pulse in the arm, whilst the other at the same time reads the leg manometer and feels the pulse in the leg. By this means one *is* able to make, as by Dr. Hill's method, simultaneous readings on the arm and leg, and it is, I think, a more accurate procedure than his, for it is difficult for one observer to feel two arteries at the same time so as to be able to appreciate any but marked differences between the times at which the two pulses reappear after these have been obliterated. However, I have found that the two methods yield substantially the same results. One word more. Dr. Hill says that his colleagues the clinicians have not affirmed that they have felt such rigid contracted arteries as Dr. Russell describes. I would say in regard to this that, although originally strongly biassed against Dr. Russell's views, the more observations I make on cases of arterial disease the more I am convinced that his published clinical observations on these cases are correct. However, it is the rule in medicine that original observations like those of Dr. Russell are slow to be accepted.

In regard to the observations on blood pressure after forced exercise, I am extremely interested to hear that Dr. Hill has obtained pressure readings as high as 220 millimetres. Perhaps the fact that his highest readings are considerably higher than any which I obtained is accounted for by the fact that by means of his new sphygmometer he *is* able to take the reading more quickly than is possible by the ordinary armlet method.—I am, Sir, yours faithfully,

OLIVER K. WILLIAMSON.

Upper Berkeley-street, W., March 27th, 1909.

THE THERAPEUTICS OF RADIUM.

To the Editor of THE LANCET.

SIR,—While appreciating the importance of Dr. N. S. Finzi's communication on the above topic which appears in THE LANCET of March 20th, I would point out that no attempt is made to elucidate the reactive changes which bring about the dissociation of the combined proteid elements of the tissue cells, for which these emanations are well known to have a selective proclivity—viz., the neuron which is of the highest molecular complexity and the neoplastic cell of lowly organisation. No mention is made as to the method of estimating dosage by filtration or the nature of the media used. The first observations made with radium were necessarily made under conditions of filtration, which for efficiency of action have of late been eliminated. While on the other hand this method has been adopted with advantage for x ray effects, both deep and superficial. In a contribution to THE LANCET of Jan. 26th, 1907, I made an attempt to throw some light on the therapeutics of this subject controlled by a series of opsonic estimations against the bacillus of tuberculosis, since when my observations have received confirmation by Dr. Lawrence and Dr. Crane of the United States of America and by M. Paoli and M. Nuncioni of Italy.

The wealth of clinical results that have accumulated during the past few years by empirical treatment, urgently call for scientific elucidation, on the precise lines I have *endeavoured to suggest—namely, by opsonic estimations* whenever this is practicable. The index to the bacillus neoformans is invariably either low or excessively high during active cell proliferation in cancerous processes, and in a recent case of mine, during retrogression of the growth under the influence of the x rays, applied exclusively to the lymphatic glands, the index came up to within the normal range. By this statement I do not desire to imply that this organism is the sole causative factor, but that it plays a part in association with the causative factor, whatever this may be, is not improbable.

As far back as in 1881 the late Professor Huxley[1] announced the fact that "pathology is the analogue of the theory of perturbations in astronomy, and therapeutics resolves itself into the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy. It will, in short, become possible to introduce into the economy a molecular mechanism which, like a very cunningly contrived torpedo, shall find its way to some particular group of living elements and cause an explosion among them, leaving the rest untouched." A remarkable prediction now being fulfilled.

I am, Sir, yours faithfully,
H. D. MCCULLOCH.

New Cavendish street, W., March 23rd, 1909.

CONVENTION OF THE AMERICAN SOCIETY FOR THE STUDY OF ALCOHOL AND DRUG NARCOTICS,

HELD AT WASHINGTON, D.C., U.S.A., ON MARCH 17TH, 18TH, AND 19TH.

(FROM A SPECIAL CORRESPONDENT.)

The Alcohol Question in the United States.

ALTHOUGH the Society for the Study of Alcohol and Drug Narcotics was the first medical association in the world formed for the purpose of studying alcohol and the diseases following its use from a scientific point of view, and its organ, the *Journal of Inebriety*, has been in existence since 1876, yet the legislative control of persons addicted to alcohol in excess is still very inadequate in the United States.

It is for the purpose of enunciating the scientific bases upon which must be constructed the edifice of legislative and social control of the drink evil that this association met in Washington during the commencement of the Sixty-fourth Congress and the *régime* of the new President, Mr. Taft. The great wave of "Prohibition" which has passed over the South during the previous five years has prepared the public and the legislators for a serious consideration of the means of controlling what is felt to be a menace to the future of the nation. Indeed, to this theme the Presidential address of Dr. MARCY of Boston was limited. He stated that in the North ter [illegible] whereas in the South it was being [illegible]. Economic forces were at the root [illegible]. these had enlisted the active support of the moral forces which always opposed alcoholic excess. The movement needed leaders, not mere theorists, and for the practical teaching physicians were required. The Society for the Study of Alcohol endeavoured as an organisation to represent the spirit of service which would eventually be required for national life. The impelling motive in the South arose from its rapid industrial growth at the end of the reconstruction period after the termination of the civil war. For this growth the efficiency of the labouring population must be maintained. *Of the 36,000,000 population of the South* 20,000,000 were negroes; and of the remaining 16,000,000 80 per cent. were native born Southerners whose education had in the main been greatly interfered with as a consequence of the poverty following the war. The educated leaders had seen the need of imposing a restraint, and pending education Prohibition was suggested. The movement was very early supported by newspapers and in the counties cross-road drinking shops were abolished. In Georgia, before state prohibition was declared, 120 out of 145 counties had already excluded saloons. The vote for the measure was opposed in the House by only seven out of 134 members, and in the Senate by 39 out of 139. The measures prohibited the manufacture, sale, and keeping in shops of all intoxicants; even druggists and physicians might keep only pure alcohol, and might supply only one pint upon one prescription, which could not be repeated. But the law was nul [illegible] importation of wine, [illegible] (Your correspondent [illegible] imported last year alone into Georgia.) In Alabama, however, not only had there been county and State prohibition (the Bill for which passed with only three dissentients) but an Anti-shipping Bill was passed with but five dissentients. In Mississippi the law was similar, with the difference that although sacramental wine and home brewing were not unlawful *no one* might be in possession of more than two quarts of liquor. Oklahoma became a state during the Prohibition movement and had the most drastic of all the laws, for a medical man who was convicted of prescribing alcohol for other than medical purposes might be *sentenced* to imprisonment. Of the non-Prohibition states in the South very few counties remained without restrictions. Even in Kentucky, the centre of whisky manufacture, all the counties but four had restrictions. In Tennessee only a few towns were exempt. In West Virginia 33 out of 55 counties had Prohibition; in Virginia, 46 out of 100, as well as 20 partially; in North Carolina, 66 out of 97. In Atlanta, the chief city in Georgia, railway accidents had diminished 20 per cent. since Prohibition had been introduced. The arrests for drunken and disorderly conduct were only 66 last year, a colossal diminution, and the race riots had entirely ceased. None of the Prohibition measures had been party questions, both Democrats and Republicans participating. The real efficacy of Prohibition was proved by the great diminution of internal revenue stamps which had caused the discharge or transference to other work of a number of employees in the Government printing office in Washington. It should not be forgotten that prohibition to be real must conform to public sentiment and this could not be maintained by abstract teaching in school.

Dr. CROTHERS, the secretary of the association, perhaps the best known figure in the American movement against inebriety, in discussing the future of the alcohol problem, said that the Prohibition movement did not depend upon hysteria but was a universal consciousness of the evil of inebriety. The movement against alcohol was not a moral but a physiological one. Alcohol had a future as a fuel for the small engine. This was the direction that the liquor interests should follow so as to meet the demand when the saloons had been abolished.

Dr. BARIGHT (New York) stated that America was 15 years behind Germany, which had declared the uselessness of alcohol in medicine.

After a statement that it was the fusel oil which made it useful in snake poisoning, Dr. WILLIAMS (Washington) stated that recent research has shown the entire inefficacy of alcohol as an antidote to snake poison. He urged a conservative attitude towards the use of alcohol in therapeutics, believing that much careful experiment in the laboratory of the pharmacologist and at the bedside by therapeutists was still required.

Dr. PARKS (Georgia), editor of the *Altruist*, stated that [illegible]cent court decisions with regard to what is known as "near [illegible]er" had much diminished the benefits which Prohibition [illegible]st brought in Atlanta. This preparation contained a good deal of alcohol, and was being largely consumed since its sale had been pronounced legal.

Dr. KELLY (New York), in discussing the alcohol problem in everyday life, highly commended a series of magazine articles which Dr. Henry Smith Williams had communicated to *Maclure's Monthly*. Dr. Kelly thought that alcohol should be classed with cocaine as a dangerous drug. From his operative experience as a gynæcologist he knew the pernicious effects of 'moderate' drinking. Alcohol was the most common cause of the lack of moral training in childhood.

Dr. ROSENWASSER (Newark, N.J.), chairman of the New Jersey Commission on Crime and Dependency, disagreed with prohibition. Local option was worse still.

Mr. CRAFTS (Maine) stated that no human regulation could be universally enforced: the law did not prevent murder, thieving, or forgery, but it diminished them. Prohibition diminished drunkenness.

In discussing the rational treatment of inebriates, Dr. ROSENWASSER laid great stress on communal effort. He animadverted upon the fact that at present only those who were already drunkards could be admitted for treatment, and that no accommodation was made for voluntary applicants. Retreats should be supplied for early hopeful cases. The criminal acts of epileptics, too, were a sufficient cause for commitment in most States. Why should not the same principle apply to the victims of alcohol? The early segregation of modern treatment had improved the prognosis of insanity, and a similar procedure would even more improve the prognosis of inebriety.

Dr. KELLOG (Battle Creek) agreed that the chronic inebriate was a neurasthenic with disturbed metabolism. The remedy was not to regard inebriety as a vice but to treat it medically as a physical perversion.

Dr. KEISTER (Virginia), in discussing the effect of alcohol stated that in the Boer war the Boers who displayed much stamina took no alcohol, while Sir Frederick Treves had said that in the march of the British army to relieve Ladysmith during the great heat the men who dropped out were the drinkers of alcohol. In the United States there were 3,500,000 hard drinkers, of whom 125,000 died annually, 5000 by suicide. Alcohol cost the country incalculable sums of money; it was responsible for 85 per cent. of the crimes, 75 per cent. of the paupers, 50 per cent. of the insane, 40 per cent. of liver and kidney diseases, and 75 per cent. of fashionable ailments. 60 per cent. of the children who were in epileptic, imbecile, or reform institutions were the descendants of drunken parents or grandparents.

The difficulties in the way of preventing this national danger were indicated by Dr. WILEY, chief chemist of the U.S. Bureau of Agriculture, who related his experiences in helping to make and to enforce pure food laws which now compelled all medicines that contained alcohol to be labelled with the percentage they contained. Dr. Wiley's assistant spoke of the prevalence of the so-called "soft drink" habit in the Prohibition States of the South where cocaine and caffeine were sold under more than 100 fancy names and created innumerable victims among the factory and shop girls, soldiers, and clerks. Another source of the drug habit was the sale of drugs by post in secret packages as a cure for various habits, and diseases and as headache powders. To a circular sent to 856 physicians asking them to report cases of addiction to such drugs 814 replied and reported cases of poisoning, with 28 deaths and 136 cases of habitual use.

In reply, Dr. ROSENWASSER declared that the sale of these alleged cures was merely an excuse to make money by selling at a high price to habitués the drugs for which they craved but which they could not legally obtain otherwise. He declared that these firms were doing a good business in spite of the exposures which were made some time ago in the lay press. The government chemist stated that they could stop this illicit traffic if a united medical opinion declared itself against the pretensions of the dealers. A Bill was at present before Congress to prohibit the inter-State traffic in habit-forming drugs except wholesale to pharmacists. If this were disallowed and pedlars were prohibited the individual States would be able to control the problem within their own borders.

(To be continued.)

MOSQUITOES AND MALARIA: A CAMPAIGN THAT FAILED.

(FROM A SPECIAL CORRESPONDENT.)

A LEADING article dealing with the Story of Malaria in Mauritius, which appeared in THE LANCET of March 27th (pp. 926-28), recommended anti-malarial measures chiefly directed towards mosquito extermination at an annual cost of £9000. As these recommendations are based on the favourable results obtained consequent to observance of the same procedure at Ismailia, the Federated Malay States, Hong-Kong, and the Panama Canal zone, no doubt the record of an instance of failure in India will not be without interest to the medical advisers of those administering fever-stricken localities before they recommend large expenditure of public funds for what may produce doubtful results. Lahore Cantonments (Mian Mir) when selected as an area for British troops in the pre-Mutiny days was a healthy station, free from marshes and situated on a dry sandy soil 700 feet above sea level. During the process of inhabitation it was irrigated to improve its grass and vegetation, and 40 years after the Mutiny we find it densely grown over with vegetation and closely irrigated. The inhabitants, both civilian, military, and native, were intensely afflicted with malaria. In 1901, at the instance of the Sanitary Commissioner, the Government of India appointed two experts in the subject of malaria prevention—Major S. P. James and Captain S. R. Christophers, I.M.S.—to visit Mian Mir, and an active campaign was undertaken against the breeding-places of the anopheline mosquito. This campaign proceeding strenuously and continuously for years received a most intense and unexpected stimulus on the appointment of General Walter Kitchener, C.B., to command the Lahore Division in 1904, and neither money nor labour was spared. General Kitchener threw himself heart and soul into the work and the following measures were carried out.

(1) Large works of surface drainage were carried out by the Royal Engineers and irrigation was completely abolished throughout the cantonment, (2) with the abolition of irrigation every canal, ditch and channel which had been used for that purpose was filled up permanently, and every pool and depression within half a mile of any house in the cantonment was also filled up levelled, or drained, and (3) mosquito brigade measures were not discontinued when the experiments of Major James and Captain Christophers were over, but were extended with great thoroughness throughout the cantonment An interesting feature of the campaign was the employment of all the British and native troops of the garrison (about 2000 in number) on the work of filling in the canals and ditches That the experiment has been effected at great sacrifice to every inhabitant of the cantonment none who visits it can doubt for the abolition of irrigation resulted in the almost total extinction of gardens In experiments of this kind there is a danger that the restriction of cultivation and the compulsory abolition of nearly all vegetation will restrict the amenities of life to such an extent as to render the cantonment uninhabitable by man It will be remembered that the method upon which Major James and Captain Christophers relied for ascertaining whether there has been an increase or decrease in larvæ and adult insects depended upon the fact that (to an observer who is skilful in detecting these insects and who has regularly collected them in specified places) a decrease or increase in these places must be obvious This test still remains the best that has been employed in any anti mosquito operations, the only other which has been used being what is called "the general consensus of opinion," which means, of course, the opinion of the irresponsible and untrained crowd Major James has now given us his conclusions in a communication read before the Bombay Medical Congress he does not think the problem of whether there has occurred a diminution in the number of larvæ in the cantonment needs discussion, because it is certain that by the abolition of irrigation, the filling in of all pools and depressions, and the other works mentioned the number of breeding places has been enormously reduced

Mosquito birth rate —Major James did not see the condition of the cantonment during the rains of 1908 but at a visit in October, although he searched the most likely parts of the cantonment every day for four days he could find only three breeding places and only one of these —a burrow pit situated at a distance of more than half a mile from the nearest house in the cantonment—was of considerable extent He thinks there can be no doubt that, to quote an expression often used by Professor Ronald Ross, "the birth rate of anopheline mosquitoes in the area has been enormously reduced To the question whether there has been a marked reduction in the numbers of anopheline adults he cannot give such a satisfactory answer

Statistics —Whatever may be the opinion of those who are willing to believe that a simple statement of the admission rates from malaria during periods before and after anti mosquito operations have been conducted is sufficient proof of the success of the operations, Major James feels sure that everyone in India is too well acquainted with the fallacies inevitable in such statistics to be content with such a form of proof And if one can provide no other evidence than hospital statistics these should be subjected to a very careful and detailed analysis before being regarded as of any value In the Statistical Office of the Government of India there are great facilities for an analysis of this nature and as regards the statistics of Mian Mir, Major James (who is the Government official responsible for medical statistics in India) caused one to be made He is afraid even the most strenuous advocate of anti mosquito operations could not infer from it either that the diseases which some years ago would have been diagnosed as malaria have been markedly reduced, or that the general health of troops in the station has been greatly improved While Major James believes that these statistics are the most accurate that can be obtained, it is necessary to point out that no official statistics regarding malarial fever represent at all accurately the true prevalence of the disease among troops During October, 1908 more than half the British soldiers in Mian Mir were either admitted into hospital or were being treated as out patients for malarial fever alone, to say nothing of the admissions for "debility" the result of that disease, but even this statement represents very inadequately the havoc wrought by the epidemic There are many British and native soldiers who do not report that they are ill unless it is quite impossible for them to carry on their duties, and it is probable that among such men the proportion infected with malaria parasites is high, because 'a touch of fever' is regarded very lightly by them Owing to this practice of not reporting sick unless quite incapacitated it often happens that the true condition of a regiment is not apparent unless the regiment is suddenly called upon to perform a march

Examination of children —Major James dealt lastly with the prevalence of malaria as shown by the examination of native children in bazaars In his first report on the anti malarial operations in Mian Mir a number of results were given which had been obtained in October, 1901, for the purposes of this test by Dr J W W Stephens, Captain Christophers, and Major James in their preliminary survey of Mian Mir Cantonment The figures which are of importance at present are reproduced from the first report and are as follows —

Locality	Time of year	Percentage of children infected with malaria parasites (endemic index)	Per cent with enlarged spleens (splenic index)	Number examined
	1901			
British Infantry Bazaar	October	51	80	25
Royal Artillery Bazaar	,	35	75	26
Native Cavalry Lines		24	36	25
Syce Lines A	November	56	48	25
Syce Lines B		20	20	25

For the whole cantonment the actual numbers and percentage worked out as follows —

Date	Number of children examined	Number infected with malaria parasites	Number with enlarged spleens	Endemic index	Splenic index
October and November 1901	123	48	67	37 5	52 3

These figures are of permanent value because it must be obvious that if anyone eventually succeeds in extirpating, or materially reducing, malaria in Mian Mir such a result will be evident by a great reduction in the figures It may also be said that until a marked and permanent reduction in the figures occurs no one should be entitled to say (whatever hospital statistics may appear to show) that the malarious nature of the cantonment had been materially improved Anti mosquito operations have now been carried on continuously in Mian Mir for more than six years, during more than three of which irrigation has been entirely abolished, and one was entitled to expect that by this time if the operations had been successful the figures would have fallen almost if not quite to zero No serious objection has been, or can be, urged against the value of this test as a means of proving whether anti malarial operations have been successful or not and it was therefore natural that when Major James visited Mian Mir with the object of confirming, if possible the favourable accounts regarding the success of anti mosquito operations in that cantonment he should turn to it first

For the last three years it has been the practice to give quinine twice weekly not only to all troops and followers but also to their families and to the children in the bazaars During Major James's visit he found that a hospital assistant was on duty solely for the purpose of administering quinine to children in the British infantry and Sudder bazaars In the lines of native regiments the quinine was administered to the children by the hospital assistants attached to the different regiments Major James, being aware of the arrangements and having seen the children in the native cavalry lines receive their doses, was surprised to find so many children heavily infected with malaria parasites.

Disappointing results.—Major James has drawn up the following tables regarding parasite and spleen rates in Mian Mir since anti-malarial operations were begun in that cantonment:—

I.—*Mian Mir as a Whole.*

—	October, November, 1901.	October, 1908.
Parasite rate per cent. (endemic index)	37·5	81
Spleen rate per cent. (splenic index)	52	69
Number examined	For parasites, 128 For spleens, 128	For parasites, 147 For spleens, 147

II.—*Specified Localities in Mian Mir.*

—	—	Oct., 1901.	Oct., 1902.	Oct., 1903.	Oct., 1908.
British Infantry Bazaar	Endemic index	52	41	—	68
	Splenic index	80	69	77·5	64
Royal Artillery Bazaar ...	Endemic index	65	20	—	78
	Splenic index	75	64	64·5	—
Royal Artillery Hospital, Followers and Syce Lines	Endemic index	56	—	—	80
	Splenic index	48	—	60	85
Native Cavalry Lines ...	Endemic index	25	—	—	85
	Splenic index	36	—	—	55
Native Infantry Lines (Dogras)	Endemic index	—	—	—	95
	Splenic index	—	—	—	79
Native Infantry Lines (Pioneers)	Endemic index	—	—	—	83
	Splenic index	—	—	—	74

From whatever standpoint these figures are regarded the answer is as unequivocal as it is disappointing. It was hoped that it might at least have been possible to say that the anti-mosquito operations had mitigated, though they had not prevented, the epidemic, but if we consider for a moment that although many of the children whose blood was examined had undoubtedly been taking quinine at least once a week, parasites were present in the blood of from 68 to 95 per cent., we must conclude that the difference between a prevalence of this degree and one which is worse is inappreciable. In this opinion Major James feels sure that he will be supported by medical officers at Mian Mir who were able to observe the terrible havoc wrought by the disease among troops and followers in the cantonment.

The lessons to be learned from the Mian Mir experiments are extremely important from the point of view of the military authorities and from that of administrators in general. It is not intended to refer to them here. The authorities (who aimed, of course, at the prevention of malaria) have carried out a system which has not only proved ineffective for the purpose they had in view, but has resulted in reconverting the cantonment into the arid desert which it was 50 years ago. In view that the results of these operations may tend to arrest enthusiasm in the great cause of the prevention of malaria, it may be noted that anti-malarial measures and mosquito-destruction measures are not, and have never been, synonymous terms, except to those who regard the latter as the only method of value for reducing malaria; and that in Major James's opinion enthusiasm in the anti-malarial cause is not arrested by the somewhat rare instances when the *truth* regarding failure in mosquito-destruction operations has been proclaimed, but by the more frequent ones when success in such operations has been reported on evidence that will not bear criticism and is often ridiculous.

Captain Christophers, speaking on Major James's paper, said they knew from Panama that they could deal with malaria, but what they wanted to know was which particular method was the best. In Mian Mir he thought that they had set about it in the wrong way, and that instead of having a campaign against mosquitoes they should have pushed the use of quinine.

A CRISIS IN THE WATER-SUPPLY OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AN UNPOPULAR WATER-SUPPLY.—A CHORUS OF COMPLAINTS.—A SINISTER WARNING FROM BRESLAU.—EXTENSIVE CONSUMPTION OF UNFILTERED NILE WATER AND ITS RISKS.

Cairo.

OF the numerous sanitary problems that have to be studied at Cairo, the drainage scheme which has just been accepted and sanctioned seemed likely to hold the first place in the public mind. A few hours in Cairo sufficed, however, to show that in forming this opinion I was quite mistaken. Outside the official circle no one really knows anything about the scheme for laying sewers in Cairo. Most persons content themselves with the expression of vague apprehensions which are, however, easily quieted by the conviction that this is still a question for the future. The public is somewhat sceptical, however, as to that future being very immediate. The present is the tenth or twelfth project for draining Cairo, and in spite of assurances year after year to the contrary nothing whatsoever is done. Indeed, what was the use of talking about drainage schemes before sufficient water was provided to flush the drains. On the other hand, everyone, from the highest to the lowest, is intensely interested in this question of a water-supply. Most persons have an opinion, generally a very strong opinion, on the matter, and on all sides there is a great clamour demanding immediate action. So widespread is the interest taken that the water-supply is no longer merely a sanitary and scientific problem. It has acquired a political and sentimental aspect with which it is now necessary to reckon. Among the native population there is a superstition against drinking what they denominate "dead water." They will often prefer to drink extremely foul surface water to a pure water coming from underground where they say it is dead and buried. Thus from the very beginning there was a prejudice against the present supply, because it is pumped out of wells. So much is this the case that when the first complaints were made they were left unheeded, being attributed merely to this prejudice. In a little while, however, the Europeans who had no special reason for objecting to well water also began to complain and now it may be said that everyone is dissatisfied. Consequently, I had hardly reached Cairo when first one person, then another, and finally quite a chorus of people expressed their hope that I would investigate the question of the water-supply. Egyptians and Europeans are all eager in regard to this matter, and some did not fail to express themselves with considerable bitterness of feeling.

The present difficulty is due to the abandonment of the Nile as the direct source of supply for Cairo—indirectly almost all water in Egypt is Nile water. Obviously, the Nile waters are often contaminated, and it was also equally evident that the methods of filtering employed at Cairo were defective. It was therefore dangerous to drink the Nile water. The fact that an employee at the Nile filtering works at Alexandria died from cholera helped to create a scare. The present water-supply of Cairo is the outcome of panic rather than of a very complete and deliberate investigation. It happened that at Tanta, a town which is half-way between Cairo and Alexandria, and which has a population of 60,000, wells had been dug to a depth of 150 to 160 feet, which yielded a very good water-supply. This water was pure and free from bacteria; and the inhabitants, in spite of their preference for the Nile and surface waters, soon recognised the merits of the new supply and were quite content. The Government then thought something similar might be done for Cairo and made borings near the National Hotel, but the results were unfavourable. At Rod-el-Farag, some couple of miles down the Nile, and beyond Cairo they found what seemed to be very good water. For a whole year pumping operations were carried on here to see if the supply would diminish and it did not. The Government then proposed to the Cairo Water Company that it should transfer its works to Rod-el-Farag, dig a large number of wells, cease filtering the Nile water, and supply well water in its stead. This was done, and a few days ago I visited the installation.

There are in all 22 wells, but they are not all finished.

At present 19 wells are in working order. As the primary object was to avoid drinking the Nile water I was surprised to find that the wells are all along the bank of the Nile, and this, too, after the river has passed through Cairo. Four of the wells are close to the river and the others are at a distance of 330 yards from the water's edge. The wells follow the river in its northerly course and are separated one from the other by a distance of about 88 yards. The water company only owns a strip of land 12 metres wide running the length of the 22 wells. On either side of this strip the land is cultivated and manured. There are a village and an old Mohammedan cemetery close to the wells. Each well consists of a 13-inch wrought-iron bore-pipe, going down a distance of 30 metres. The various portions of this pipe are joined together by being screwed into an iron socket to render them thoroughly watertight. Below and for a distance of another 30 metres is the intake. This consists of a tube-shaped frame on which are affixed three layers of gun-metal wire gauze that act as a strainer or rough filter. Two tubes were inserted. Along the inner tube was put the wire strainer. Outside of it some fine sand was introduced. Then the tubes being removed the water enters after passing through the layer of sand and the gun metal wire gauze strainers. But, of course, the water does not flow in an absolutely horizontal line towards these 30 metres of intake tubing. The action of the pumping must draw down the water from a higher level. Therefore, it cannot be said that the water is taken 30 metres below the surface of the soil, the level at which it enters the tube. Further, it is natural to suppose that the more frequent and energetic the pumping the higher will be the level from which the water is drawn down. The soil above consists first of a deposit of Nile mud. It is the fertile earth mud of the Nile and descends a depth of about 4 metres. Then come some 2½ metres of light clay mixed with sand. Below this there is sand, some of it very fine sand, with occasional layers of gravel.

Thus we have at a depth of 30 to 60 metres 30 metres of intake pipe. Above there are 30 metres of water-tight pipes which are the pump-pipes, and these empty into a main syphon-pipe connected with all the wells. In this main the waters from the different wells mix; but above each well there is an inspection chamber where there is a valve, by which the connexion with any one of the wells can be cut off, so that the supply from that source ceases. The hardest pumping, I was assured, would not reduce the level of the water round the pipes more than 1½ metres. But if the level of the subsoil water is not reduced more than a few feet, may not some of the water obtained have travelled downwards from a greater distance, and have come from points further removed from the wells? Obviously, the well water is Nile water which has changed very considerably in consequence of the distance it has travelled through the soil. Its character now depends on the nature of the soil through which it passes; and it seems to me that the extent of this catchment ground will of necessity vary according to the amount of water pumped out. The first trial well which was constructed yielded 5000 cubic metres of water per day. When eight wells had been dug and brought into operation the yield per well was less, and this was attributed to their proximity to one another. It was therefore decided not to sink wells with less than 80 metres between them. Even under those conditions the amount of water that each well would yield was no longer estimated at 5000 cubic metres, but 4000 cubic metres per well were set down as the normal quantity that might be expected. It does seem to me that there was not sufficient forethought displayed as to the possible effects of increasing the volume of water extracted, seeing tl [illegible] was extended the quality of [illegible] the quantity. Because one v [illegible] day of good water,' it does not follow that 22 wells, sunk close to each other, are going to yield every day between them some 88,000 cubic metres of water of identically the same quality. Again, it would seem as if the fear of pathogenic bacteria was allowed to eclipse all other considerations. The water was hard; it was found to contain some manganese and some iron, which increased as the number of wells increased, but this was considered inoffensive.

In a short time it became evident that this well water was not only hard but that it was extracting iron out of the pipes through which it passed. At times, notably in the baths, the water was found full of heavy matter in suspension and quite dirty in colour. No one had ever complained of iron in the Nile water nor had any accidents happened to the delivery pipes when they were used to carry the Nile water. But now that the well water travels in these pipes all kinds of mishaps occur. The fact is that deposits take place in the pipes and these are washed away by any irregularity in the running, such as by a sudden increase of speed or by the sudden stopping and recommencing of the flow. Hence the trouble is often noticed in bathrooms where the water is not tur [illegible] water has opportur [illegible] the bath. At the [illegible] had not been used for four months was opened for my edification. The water that came out first looked a dark brown colour. In an ordinary hand-basin it left a heavy deposit of dark hard particles and a considerable quantity of sand. This I was able to scoop up with my fingers after the water had stood only a few minutes. The water had also an unpleasant odour. But after the tap had been left running for five minutes or so the water seemed quite clear and free from odour.

The general belief now prevalent is that a vegetable growth called the *crenothrix*, the existence of which in the water is favoured by the presence of manganese and iron, causes the greater part of the mischief. These growths help to block up the pipes and add to the quantity of organic matter in the water. In these circumstances the official analysis of the water as found at the wells is no longer sufficient. What is wanted is analysis of the water after it has travelled a long distance and remained for some time in the distributing pipes. These pipes, which are far from perfect in construction, add to the difficulty. In the absence of sewers, also, there is a quantity of "dead ends" or *cul de sacs* where the water stagnates in the pipes. In regard to this vegetable growth M. Villiers and M. Colin in their work on the "Altérations et Falsifications des Substances Alimentaires" (Paris, 1900) when dealing with water-supply speak of the *crenothrix Kühniana* in the following terms: "This white water weed, which may be found in ordinary water, is very common in water that contains organic matter in decomposition or in chalybeate waters. It has a strong affinity for iron salts, especially the oxide, and fixes this oxide in its filaments. Thus it forms felt-like masses, brown in colour, and large enough to obstruct water pipes completely. This has been noticed at Lille by M. Girard and at Bordeaux by M. Tieman and M. Gartner. In decomposing these brown masses impart to the water a russet tint and a disagreeable taste and odour. The water is then unfit for drinking purposes."

This description coincides with what is now occurring at Cairo when water is drawn from a pipe in which it has been allowed to stagnate for some time. Then the manganese and deposits in the boiler pipes spoil the boilers. To remedy these evils, at a cost of about £900, four big filters have been constructed. The idea is to pass the water through small pieces of the ore of peroxide of manganese on which the manganese is precipitated. Then the ore can be re-oxidised by exposure to the action of the sun. But to clean these filters it is only necessary to increase the pressure of the water which will wash the dark-coloured precipitate off the filtering media. Thus the filters would themselves create the nuisance which they are intended to prevent if, in consequence of a fire or from some other cause, the water were drawn from them more rapidly than usual. Then, the four big filters now under trial cannot filter more than 400 cubic metres per day, and therefore it would require an enormous plant and a very large outlay to apply this doubtful process.

A more serious consideration, perhaps, than the defective quality of the water is the fact that the supply may also fail in quantity. We have seen that the first well yielded 5000 cubic metres per day and that when several wells were dug it was necessary to reduce the estimate to only 4000 cubic metres per well. In the course of time it became evident that the wells were not even yielding the lower estimate of 4000 cubic metres. At last this falling off was so marked that in January, 1908, an experiment was made to discover the actual quantity obtained. To the surprise of all concerned it was found to have fallen from 4000 cubic metres per well to 3200 cubic metres. Worse than all, the decrease seemed to continue. In January, 1909, another experiment was made and the yield then amounted to only 2700 cubic metres per well. There had been a decrease of 500 cubic metres in the course of one single year.

I may refer here to the alarming experience of the town of Breslau where in very similar circumstances the water-supply suddenly collapsed. The capital of Silesia has 422,000 inhabitants, and in 1872 waterworks were installed to filter the waters of the river Oder. The results seemed excellent, and in the last ten years during which this water was drunk there were but six to 11 deaths from typhoid fever per annum per 100,000 inhabitants. But in 1892 the fear of cholera suggested that the filtered water should be replaced by underground water—in other words, natural instead of artificial filtration was demanded. Accordingly, 315 wells were dug at a distance of only 21 metres from each other. The pipes used were but six inches in diameter. By the commencement of the year 1905 the works were so advanced that nine-tenths of the supply would, it was thought, be available. But it was soon discovered that the amount of water pumped out of the wells decreased. Instead of 60,000 cubic metres they only obtained 40,000. Further, it became apparent that the water had changed in character and now contained an altogether unexpected quantity of iron. By the end of March, 1906, there was so much iron in the water that linen could not be washed. All sorts of excuses were forthcoming. Air was said to have penetrated into the water-pipes though they were ultimately proved to be perfectly watertight. Fortunately, the filters that had been used for the waters of the river Oder had not been destroyed and the town was in this emergency able to return to the old system of water-supply.

This is exactly what is wished for here in Cairo, only with better methods of filtration than those employed in the past. Except officials, whose tongues are tied and who dare not express an opinion, everybody I have encountered condemns the present water supply, and desires to return to the Nile—the Nile properly filtered be it understood, for in the absence of storage filtration would be the only safeguard. The ladies especially are very emphatic as to the existing troubles. The expenditure of soap is ruinous, and in spite of this the linen is yellow and sometimes absolutely stained. Vegetables cannot be properly cooked in this water, and so convinced are some people that the water causes the hair to become brittle and to break that they go to the trouble and expense of sending for a bucket of water from the Nile with which to wash their heads. As for the natives, they continue drinking the Nile water although it is now unfiltered. The Nile water is still distributed, but only for watering the gardens or the streets. So we have arrived at the unfortunate position that formerly the filtered Nile water was considered dangerous and the result of digging the wells to remedy matters has been that a large number of people now drink unfiltered Nile water. The intended reform has, in fact, entirely missed its mark. The danger from the Nile has been increased instead of decreased. Indeed, the death-rate of Cairo does not testify to any improvement. Among the foreigners especially, who are more likely to drink the well water than the natives, the death-rate seems to have increased rather than to have decreased since the wells came into general use in 1905. For instance, the death-rate per annum per 1000 among foreigners was 21·8 in 1901, 25·5 in 1902, 21·1 in 1903, and 25·6 in 1904. Now, in 1905, when the well water was first extensively distributed, the death-rate among foreigners was 26·1 per 1000, in 1906 it was 25·9, and in 1907 it was 27·4. Nor can I find any indication of improvement in the specific statistics relating to typhoid, typhus, and relapsing fever which are here grouped together. It would be difficult to prove that the supply of water from the Rod-el-Farag wells has caused an amelioration in the public health, whereas the entire population is clamouring against the inconveniences it occasions. If there is danger that the Nile may bring cholera to Cairo, then that danger exists to-day and in an aggravated form, because the Nile water is still drunk extensively and it is no longer filtered. Those people who drink the Nile water are sufficiently numerous to infect the whole town if they should contract cholera from the Nile.

Under all these considerations it seems to me that the continued reliance on the Rod-el-Farag well water is dangerous, and that the supply may suddenly prove insufficient. It also appears that a return to the Nile water would be expedient, if for no better reason than that it would give immense satisfaction to 99 if not to 100 per cent. of the population. Considering that the position of the British advisers to the Egyptian Government is fraught with many difficulties, and that occasions of acquiring popularity do not occur every day, it would be a pity to miss the present excellent opportunity of supporting a measure that would be so widely applauded. It is said that the Nile water is satisfactorily filtered at Alexandria We drink in London with extraordinary impunity water that receives the drainage from an area inhabited by one and a quarter millions of people. Why should not the Nile water be filtered at Cairo? It may cost money, but so does the waste of soaps, the spoilt linen, and the injured boilers, while the "mental and moral damages" caused by the irritation and resentment of a large section of the population are worth considering.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Pulmonary Tuberculosis in Manchester.

THERE are three institutions, or rather three branches of one institution, for the treatment more especially of cases of consumption from Manchester and the district around. First of all there is a commodious and well devised out-patients' department of the Manchester Hospital for Consumption and Diseases of the Throat and Chest in Hardman-street, Manchester; next comes the hospital at Bowdon for in-patients; and thirdly, the Crossley Sanatorium at Delamere. At the *thirty-fourth annual meeting of the* supporters of the Manchester Hospital for Consumption and Diseases of the Throat and Chest held on March 22nd in the Lord Mayor's parlour some *interesting particulars* were given. Mr. W. J. Crossley, M.P., who presided, said that the hospitals were always full and if they had not adopted the plan of receiving private patients he did not known how the committee could have met the expenses. From this class of patients they received last year £3905. The idea, he said, came from Germany. The hospital stands high, the winter has been hard, and those patients "who were badly hit with disease had a bad time in some respects, but those who were not badly hit seemed all the better for the hard weather." The report showed that the 90 beds were occupied all the year and the results are said to be satisfactory, the system adopted being the "open-air" treatment with a very liberal diet. The average stay of a patient is three months. The pity is that it cannot be longer, but owing to the demands for accommodation and the numbers waiting for admission the Board has been compelled to fix a limit of three months. The patients are out of doors all day, except at meal times, and usually sleep with the bedroom windows wide open. At Bowdon the 50 beds have been fully occupied during the year, but it is sad to know that a large number of applicants are always waiting for admission. All these patients belong to the working classes, and it is usually the wage-earner who is struck down, so that they are often short of the warm clothing so much needed. In the out-patients' department 11,443 were under treatment during the year, against 11,163 the previous year. The medical board call attention to the fact that so many patients apply too late for successful treatment, and say that it is better to send doubtful cases for consultation, and even to admit to the sanatorium when tuberculosis is only strongly suspected, rather than to wait, as is so often done, till the disease is too extensive to allow of recovery. At Hardman-street the want of in-patient accommodation for urgent throat cases and for acute chest diseases has been seriously felt, but the times are not at present favourable to any further extension. Altogether this institution tries to cope with a widespread and terrible scourge so far as its resources permit and is as free from what is well known as hospital abuse as it well can be.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Meetings of Liverpool Charities.

AT the forty-fifth annual meeting of the Liverpool Hospital for Consumption and Diseases of the Chest, held on March 18th at the Town-hall, the Lord Mayor, who presided, warmly commended the excellent work which was being accomplished through the medium of the hospital and its laboratory in Mount Pleasant and the sanatorium at Delamere Forest. Special emphasis was laid upon the educational value of the work in the direction of teaching tuberculous patients the best method of improving their standard of health and the means to be adopted for preventing the spread of the disease. At the annual meeting of the Liverpool Queen Victoria District Nursing Association, also held in the Town-hall, Mr. Archibald Williamson, M.P., announced that Her Royal Highness Princess Louise had consented to attend the district nursing congress to be held in Liverpool from May 12th to 14th next. At the annual meeting of the Liverpool Country Hospital for Children it was announced that an offer had been received of £4000 towards the erection of a new open-air ward, provided that a similar sum was raised by the end of June. Towards this am[illegible] tribute [illegible] had tak[illegible]

Death from Anthrax.

A death from anthrax in a labourer employed by a Liverpool firm occurred early in March. On returning from work on Feb. 24th he drew his wife's attention to what appeared to be a boil on the left side of the neck which was painful. By the following morning the swelling had developed and, rapidly becoming worse, he was removed to hospital where he died on the day following admission. At the inquest which was held on March 3rd the medical evidence was to the effect that death was due to anthrax. A representative of the firm in which the deceased was employed stated that at the works a quantity of greasy bones were regularly crushed up for the purpose of making artificial manure and fertilisers. They also used "shoddy," the refuse from old clothes. There was, however, no warrant for the suggestion that any of the goods had been contaminated with anthrax. The deceased's duties would bring him into contact both with the bones and the shoddy. The witness never thought it necessary to take precautions to cope with a possible outbreak of anthrax. Disinfectants were, however, kept on the premises to provide against cases of blood poisoning which occasionally occurred. Mr. Beard (assistant factory inspector), who watched the proceedings on behalf of the Home Office, said he did not think that anybody realised the danger of anthrax in works of this kind. The coroner thereupon remarked that it was time that precautions were taken. The managing director of the firm stated that the stuff which came from India was bone-meal which arrived already bagged and received but little handling in this country. The firm did not use much of it; they mostly used greasy bones, the greater quantity of which came from Lancashire. He handled the stuff himself daily. A verdict of death from anthrax was recorded by the jury.

Presentation to Dr. Thomas Bushby.

Dr. T. Bushby, who recently retired from the post of medical officer to the B division of police after 12 years' service, was the recipient of a pleasing souvenir of the great esteem in which he was held by the men of that division, to whom his resignation has been a matter of much regret. The presentation took the form of an antique Dutch writing bureau suitably inscribed. Superintendent Phillips spoke of the great care and courtesy Dr. Bushby had always exercised in dealing with the men. The presentation was made by the head constable who spoke in flattering terms of Dr. Bushby's high medical qualities. Dr. Bushby, in acknowledging the presentation, paid a very high compliment to the *personnel* of the men and testified to the pleasing relationship which had always existed between them.

Medical Inspection of School Children at Birkenhead.

A very encouraging first report has been issued by Dr. R. S. Marsden, supervising schools medical officer of Birkenhead, and Dr. R. O. Morris, medical officer to the educational authority of Birkenhead. The chief defects in the children inspected were: obstructed breathing, 15 per cent.; strabismus, nearly 4 per cent.; and dirty condition, 3 per cent. There had been no objection to the inspection on the part of parents, 82 per cent. of whom took a great interest in the proceedings.

March 29th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The General Infirmary.

THE annual meeting of the subscribers and friends of the General Infirmary at Leeds was held on March 18th under the chairmanship of Mr. Charles Lupton, the treasurer and chairman of the weekly board of management. Dealing with the work done during 1908 it was pointed out that the number of in-patients treated was 51 in excess of that for 1907. This number was 7137, and included 335 who were in the beds of the institution on Dec. 31st, 1907. The average number of in-patients was 365, a figure which, being within three of the figure for the preceding year, points to the fact that the institution is working at high pressure. The average number of days spent by each patient in the infirmary was 18·7. The number of deaths was 531, which gives a percentage of 7·4, or, deducting the number of cases which proved fatal within 48 hours of admission—namely, 163—a percentage mortality of 5·2. The new out-patients numbered 42,371, exclusive of 601 patients in the maternity department. The two semi-convalescent hospitals in connexion with the infirmary have been very fully utilised. Patients who required more attention than they could obtain at convalescent hospitals of the ordinary type have been sent to the number of 1154 to these two institutions, which form virtually an extension of the infirmary, where the nursing is of the same standard as at the main institution. A resident medical officer is in charge of these homes under the direction of a member of t[illegible] c[illegible] c[illegible] during the last quarter of a century a very striking illustration of that steady diminution in the use of alcohol which has been frequently referred to. During the year 1908 the total amount of stimulants used in the wards and in the theatres and casualty departments was 2021 ounces of wine and 4405 ounces of brandy, a total of 6426 ounces—that is to say, about 18 ounces among 365 patients per day. Among some of the facts mentioned by the chairman was the gratifying one that since the commencement of the out-patient maternity department in 1885 no less than 13,342 confinements had been conducted with an aggregate mortality of 34. In the out-patient room, where, as already said, over forty thousand patients presented themselves, the inquiry officer had investigated the circumstances of 13,640 applicants. Of these, 115 at once admitted their ability to pay and were not attended to; 982 cases were further inquired into and 8 per cent. of these were found unsuitable on financial grounds for treatment. Mr. Lupton made some interesting remarks on the question of pensions for nurses and servants. He reminded the meeting that as a result of the memorial to the former treasurer, Mr. R. Benson Jowitt, a sum of £2240 was set aside at the suggestion of Mr. Jowitt himself for the purpose of establishing a pension fund for nurses and old servants of the institution. Unfortunately there had been no addition to that fund; probably, owing to the fact that it was labelled "The Jowitt Pension Fund," and many people might think the fund was closed. On the suggestion of Mr. Jowitt, therefore, it had been decided to strike his name out of the title of the fund which is to be called the "Pension Fund." For many years, but especially during the last few years, the work of the electric department, including in this the use of the x rays and Finsen lamp, has been increasing. The matter has been fully gone into by the weekly board and the faculty, and at the annual meeting it was resolved, on the recommendation of the weekly board, that an electro-therapeutic department be established under the charge of an honorary officer who shall be styled the director of the electro-therapeutic department. The rules for the department, especially in so far as they deal with the position of the honorary officer, are so important that they are appended and run as follows:—

> The director of the electro-therapeutic department shall have charge of the electro-therapeutic department, which shall include: (*a*) The use of x rays, radium, Finsen light and high-frequency currents, for purposes of diagnosis and treatment; (*b*) the supervision of the photographic department; and (*c*) the supervision of all electrical apparatus used in the diagnosis and treatment of disease.
>
> No patient shall be treated in the department who has not been referred to it by a member of the honorary staff other than the director, but the electro-therapeutic treatment of all patients so referred shall be carried out by the director.

March 30th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Penalty for Selling Tuberculous Milk in Sunderland.

A DAIRYMAN was recently summoned by the Sunderland corporation for having sold milk from tuberculous cows within the borough contrary to an order made by the corporation. The magistrates held that the case was fully proved, but as the defendant appeared to be under a misapprehension and as this was the first case under the Act a fine of 20*s.* only was imposed. It was pointed out by the bench that subsequent cases might not be dealt with so leniently. The Act under which the above order was made is the Sunderland Corporation Act, 1907, Part VI. of which deals with the supply of tuberculous milk. The Act imposes penalties upon dairymen for selling milk from cows affected with tuberculous disease of the udder and requires that cows so affected shall be isolated and that all cases of tuberculous disease of the udder shall be notified. The medical officer of health is empowered to take samples of milk and to inspect cows the milk of which is to be sold in the borough, and if he has reason to suspect any cow to be suffering from tuberculosis of the udder he is authorised to take samples for examination. And further, if he is of opinion that the consumption of any milk sold in the borough is likely to cause human tuberculosis he is to make a report to the corporation, which can then serve notice on the dairyman calling upon him to show cause why an order should not be made prohibiting him from selling milk in the borough until such time as the medical officer of health is satisfied that the milk-supply is no longer likely to cause tuberculosis to persons residing in the borough. These provisions are applicable to all dairymen who sell milk in the borough, whether they reside within or beyond the borough boundaries. It is also to be noticed that the Act provides no compensation in cases where a farmer has to get rid of cows which are tuberculous and against whom an order has been made.

The Barrasford Sanatorium.

The annual meeting of the supporters of the Newcastle and Northumberland Sanatorium, Barrasford, was held recently in the library of the Royal Victoria Infirmary, Lord Armstrong, the president of the institution, being in the chair. The annual report was read by the secretary, Dr. O. W. Ogden. With regard to finances, the position at the end of 1908 was much better than at the end of 1907. The sanatorium was opened in May, 1907, and the deficit at the end of December was £2154. During 1908 this amount was reduced by £1298 to £856 as the result of an effort to raise £2000. In response to the appeal nearly £1000 were collected and Mr. J. H. Burn, who had already contributed largely to the expenses, gave an additional £500. Against this there was a further capital expenditure of £300 to complete the furnishing of the institution. An effort is to be made to pay off the deficit of £856 during the current year. The annual subscriptions had increased from £217 to £281. The institution accommodates 50 patients, and of these the Newcastle corporation has secured the use of 20 beds for one year at a cost of £100 per bed. Messrs. Armstrong, Whitworth, and Co. had supported the institution by maintaining five beds. The charge to other patients is £2 2*s.* per week. The honorary visiting physicians in their report stated that since the opening of the sanatorium in May, 1907, until Dec. 31st, 1908—a period of 20 months—90 patients had been discharged and every effort had been made to keep in touch with these persons after they left the sanatorium. They were in a position to say that of 52 male cases 22 are at work, two are ready to start work, six are *in statu quo*, six are not doing well, eight have not been heard from, and eight have died. Of 38 female cases 12 continued to improve, 13 are *in statu quo*, five are not doing well, five have not been heard from, and three have died. This is hardly an encouraging report, especially as it is a record of only 20 months' work. The test of the good which is done is the condition of the patient four years after he has left the sanatorium. Judging by the number "not doing well" and the number dead, it would seem as though admissions are not strictly limited to early cases of tuberculosis which present a reasonable chance of material benefit by a sojourn at Barrasford. If the object of the sanatorium were to be stated to be educational and to be a temporary health resort for those who are unfortunately afflicted with this distressing disease rather than the cure of the disease, it is more likely that the object would be achieved. A sanatorium for tuberculosis is in every way good, provided that its limitations be recognised. But if the charitable public be led to suppose that the persons sent to Barrasford are to be cured, and they read a report such as the above, they are very likely to think that the object for which their money was given is not being attained, with the result that their contributions will not be so readily forthcoming.

The Visit of Sir T. Lauder Brunton.

On March 18th Sir Lauder Brunton delivered an address on the Treatment of Heart Disease to the members of the Northumberland and Durham Medical Society. The library of the infirmary was well filled with medical men from the city and the neighbourhood. The address, which was very clear and most interesting, was devoted to the consideration of the treatment of those forms of heart disease which are not specially dealt with in the text-books but which are so common in practice and often so difficult to treat with success. Sir Lauder Brunton, as always, was most suggestive, and his address was full of advice and information which cannot fail to be both stimulating and helpful in the every-day practice of medicine. It is difficult, if not impossible, to summarise Sir Lauder Brunton's remarks, but if one were to state in one word the lesson of the address it would be—attention to detail, and this attention to detail in Sir Lauder Brunton's own work was well illustrated by the technique which he described when he has to take the blood pressure of a nervous patient. In the evening the members of the society entertained Sir Lauder Brunton to dinner. Over 100 members and their guests attended the dinner. In reply to the toast of his health, Sir Lauder Brunton referred to the establishment of the Research Defence Society, the objects of which are "to make known the facts as to the experiments on animals in this country, the immense importance to the welfare of mankind of such experiments, and the great saving of human life and health directly attributable to them." Sir Lauder Brunton pointed out the need of such a society to meet the unreasoned and unreasonable statements of good, nervous, and selfish people who sought to hinder the advance of medical science in this country. If experiments upon animals were disallowed by law all research in medicine would become impossible.

March 30th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Black-listed Patients.

A COMPLAINT of an unusual character was made at the last meeting of the Cardiff board of guardians by one of the district Poor-law medical officers. He stated that recently he had had an abnormal number of parish patients on his list owing to the refusal of some of the medical practitioners of the district to attend persons who made a practice of running up a bill for medical attendance with several medical men in succession and not paying any one of them. This class of person is unfortunately not confined to the Cardiff union, but it is not often that their sharp practice is met in such a determined manner as in Cardiff. Many of the persons concerned are said to be in fairly good circumstances, so that the proper steps for the guardians to take would appear to be to recover the cost of any medical attendance they may have received in consequence of having obtained an order from the relieving officer

The Winsley Sanatorium.

The sanatorium which was established four years ago at Winsley near Bath for the treatment of consumptive patients coming from the counties of Somerset, Wilts, and Gloucester, and the city of Bristol is continuing to do excellent work. Altogether 795 patients have been treated in the institution, and last year 215 were discharged, of which number 41 per cent. were considered fit to return to work, 38 per cent. were improved and many of these returned to their work, while 18 per cent. made no marked improvement. Six patients died in the sanatorium. It is satisfactory to find that there are now fewer applications than formerly for the admission of advanced and therefore unsuitable cases. It appears to be more generally recognised that the sanatorium is really only intended for those persons who have a reasonable prospect of recovery. In the recently issued report of [illegible] expressed that each succeeding [illegible] proportion of early cases as it [illegible] that consumptives, if sent to a sanatorium sufficiently early, can make complete recovery and be restored to full working capacity. Those patients who are discharged are encouraged to impress upon their friends and relatives the importance of early treatment and the danger of neglecting early symptoms of the disease. The medical board has very wisely made the rule with respect to the length of stay of patients more elastic than formerly. It originally provided for a residence of four months, but it has now been decided that at the end of two months the condition of a patient shall be considered and if he is not making satisfactory progress he is to be discharged. Although most of the beds are allocated to the districts named above there are a few available for patients from elsewhere, and quite recently arrangements have been made with the corporation of Coventry for the accommodation of six patients from that town.

Damages against an Unqualified Dentist.

At the Bridgend county court on March 11th Judge Bryn Roberts and a jury awarded the wife of a collier damages to the amount of £40 against an unqualified dentist at Cardiff. According to the evidence which was placed before the jury the assistant of the dentist, who was also unqualified, after injecting a solution of cocaine extracted from the woman six teeth. After the operation she fainted and a medical practitioner who subsequently attended her stated that for some days she was suffering from shock as the result of the injection of an unusual amount of cocaine. In giving judgment for the amount named Judge Roberts pointed out that he was not concerned with the fact that the dentist was not qualified, but it was reasonable to assume that the same care and skill would not be brought to bear by unqualified persons as by those who were qualified.

Cardiff Model Lodging-house.

There are in the borough of Cardiff many excellent municipal institutions, including isolation hospitals, public markets, and public slaughter-houses, but any proposals to establish a municipal lodging-house have met with no support. In a town of the character of Cardiff, with a large shifting population, connected on the one hand with the shipping and on the other with the colliery industries in the Merthyr and Rhondda coalfields, accommodation suitable for wayfarers is very necessary. The need is fairly well met, but as all the existing lodging-houses are in the hands of private individuals constant and vigilant inspection is necessary. There has recently been opened a lodging-house with accommodation for 287 men. The design of the building and the mode of carrying it on are very much on the lines of the houses which were first erected by Lord Rowton and later by the London County Council and municipalities elsewhere. Each lodger has a cubicle to himself and he has the use of the kitchens with cooking utensils and of the bathing and washing rooms. Food can be bought on the premises, but alcoholic drinks are prohibited. The charge per night varies from 6*d.* to 8*d.* The undertaking has been carried out by a limited liability company, the shareholders of which are all connected with Cardiff. One indirect effect of the establishing of this house will no doubt be the endeavour to bring up to its level of comfort other common lodging-houses in the town.

Cardiff Public Health Expenditure.

As the estimated expenditure during the next financial year necessitated an increased rate of 6*d.* in the £, it was only to be expected that the members of the city council should endeavour to cut down certain departmental estimates. An attempt, fortunately unsuccessful, was made to reduce the estimate of the health committee, which includes the charges for scavenging. One suggested reduction was particularly inopportune—namely, that of £200 for spraying the streets with tar. At a meeting of the public works committee held a few weeks ago the city engineer reported most favourably upon this method of keeping down dust both on account of its effectiveness and from the point of view of reducing the cost of maintenance. The estimated cost of the city asylum is £6000, a very considerable reduction upon the amount actually spent (£14,000) two years ago when the Cardiff lunatics were boarded out in various institutions all over the country.

March 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Notification of Phthisis.

THE following is a list of local authorities that have extended the Infectious Diseases (Notification) Act, 1889, to pulmonary phthisis with the approval of the Local Government Board up to March 1st, 1909: Clackmannan county, Kirkcaldy, Cupar, St. Andrews, Kinross county, Lower, Middle and Upper Wards of Lanarkshire, Bathgate, Linlithg[illegible]. Crail, D[illegible] North [illegible]try.

Marine Biological Association of the West of Scotland.

The annual report of this association for the year 1908 has just been issued and from its perusal it is evident that the facilities for study and research have been maintained in excellent order. During the year the tables in the research laboratory at Millport were used by 20 workers. The committee has recently issued an invitation to universities and scientific societies to send workers to Millport. The opportunity afforded to universities and scientific institutions to purchase specimens and material is being more fully taken [illegible] value of this [illegible]owledged by [illegible]ctory. The endowment fund remains at the same figure as at the end of the previous year, but the income for the year was not nearly sufficient to meet the expenditure. Not only was the whole income spent but a balance of cash in hand at the close of the year 1907 amounting to £188 was exhausted. To secure the continued prosperity of an association requiring to keep up such a large establishment as the station at Millport it is practically a necessity that a substantial endowment fund should be formed.

The Incorporated Glasgow Dental Hospital.

At the close of the session of the Incorporated Glasgow Dental Hospital Sir James Fleming, chairman of the board of governors, presided at the distribution of prizes and certificates on March 16th. In his opening remarks he said that the Glasgow Dental Hospital had been in existence for a considerable time and it had accomplished a great deal of very good work. Last year there had been over 13,000 patients treated, 80 per cent. of whom had had conservative operations, and only 20 per cent. extractions. The one thing which concerned the directors was the want of money. Their subscriptions had only reached £100, and but for the real work done by gentlemen prominent in the profession they could not have accomplished what they had, and the consequence was that the real work was left to their dental colleagues, who had given time freely both in connexion with the hospital and the school. Their desire was to bring [illegible]

of the future lay in the hands of the present-day [illegible]
urged them to maintain its high traditions and reputation.
Sir Hector Cameron then spoke. He traced the influence of
the Dental Act of 1878 in establishing and purifying the
dental profession. He held that there was in the Act
abundant means for maintaining the honour and high

traditions now entertained by all dentists. That Act had also had a very great effect upon the character of dentistry as a profession. It had produced a very great change in public opinion and in the opinion of leading and important bodies. Sir Hector Cameron then spoke of the evils arising from neglect of the teeth, adding that the workers in the Dental Hospital had realised that their work was added to by the increasing care of the War Office. No recruit would be admitted to the army if he were crippled in respect to his teeth. Soldiers in Glasgow were constantly sent to the Dental Hospital and that fact in no little manner had increased the work involved upon the Dental Hospital. Professor W. Glaister also spoke, after which the chairman called upon Mrs. McInnes Shaw to present the prizes and certificates.

University of St. Andrews: Resignation of Professor Purdie.

A meeting of the St. Andrews University Court was held at St. Andrews on March 19th, when a petition was submitted from Professor Thomas Purdie, LL.D., asking leave to retire at the end of the summer session from the chair of chemistry in the United College, owing to ill-health. The court unanimously agreed to record in the minutes the sense of the loss which the University will suffer by the withdrawal of Professor Purdie from active teaching in the chemistry department of St. Andrews. It was also agreed that steps should be taken to arrange for the election of a successor to Professor Purdie.

Montrose Asylum Charter.

At the instigation of the Secretary for Scotland, and following upon the recent agitation, the General Board of Lunacy has written to the Montrose Asylum and Infirmary Board suggesting to it that it should consider the advisability of applying for a new charter and asking for the views of the board either at a conference or in writing.

University of Aberdeen: The Chair of Surgery.

The winter session at the University of Aberdeen closed on March 24th. The graduation ceremony will take place on April 6th. The preliminary examination commenced on March 26th, 40 candidates presenting themselves in medicine. For the professorship in surgery, which will become vacant by the resignation of Professor Alexander Ogston, the following gentlemen, it is understood, are candidates: Mr. J. Scott Riddell, M.V.O., M.A., M.B. Aberd., senior surgeon to the Aberdeen Royal Infirmary; Mr. J. Marnoch, M.A., M.B. Aberd., surgeon to the Aberdeen Royal Infirmary; Mr. H. M. W. Gray, M.B. Aberd., F.R.C.S. Edin., surgeon to the Aberdeen Royal Infirmary; and Mr. Alexandar Don, M.A., M.B. Aberd., F.R.C.S. Edin., surgeon to the Dundee Royal Infirmary.

Aberdeen Trades Council and the Infirmary Contracts.

At a meeting of the Aberdeen Trades Council held on March 24th a letter was read from the clerk of the infirmary board in reply to the council's request that all infirmary contracts should be given to firms conforming to trades union conditions. The letter stated that as the infirmary was a philanthropic institution, supported by all classes of the community and utilised by the sick poor without any distinction, the directors could not see their way to grant the request. The following motion was then, on the proposition of the chairman, submitted to the meeting and after discussion carried by a majority:—

> That the Trades Council, representing the organised workers of Aberdeen, records its emphatic protest against the attitude adopted by the directors of the Aberdeen Royal Infirmary in refusing to stipulate that successful contractors must pay the trade union rate of wages and conform to all other conditions agreed upon by employers' and workmen's associations, thus admitting the possibility of firms executing work for the institution under conditions which can only tend to render these workers liable to the disease which the infirmary's primary object should be to combat, besides being a breach of a principle which has been accepted with advantage by most public and semi-public bodies in the country.

Death of Dr. Patrick Blaikie Smith.

Dr. Patrick Blaikie Smith died at San Remo on March 24th. He was born in Aberdeen in 1849 and graduated with highest honours at the University of Aberdeen in 1870. After graduation he was appointed assistant resident physician to the Middlesex Hospital, London. In 1872 he began private practice in Aberdeen and was appointed assistant to the late Professor Brazier, teacher of chemistry at the University in 1873. He was appointed physician to the dispensary, and from 1875 to 1886 was anæsthetist at the Royal Infirmary, when he became an assistant phy in that institution. In the following year he was app one of the physicians and lecturers on clinical me From 1889 to 1892 Dr. Blaikie Smith was examiner in logy at the University of Aberdeen, and from time t physician to various institutions in the city, and found t contribute many valuable papers to the medical journa 1884 he brought out his ether inhaler which obviated of the difficulties of administering ether. He had large private practice. He was also an enthu Volunteer, eventually holding the commission of Su Lieutenant-Colonel in the 1st V.B. Gordon Highlande 1895 Dr. Blaikie Smith's health was so bad that he g practice in Aberdeen and thereafter spent the winters Remo, where he built up an extensive practice. summers he spent at Nairn, visiting Aberdeen freq He is survived by Mrs. Blaikie Smith and two daught only son having died at San Remo last year.

March 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Drinking in Ireland.

THE Chief Secretary's Office for Ireland has ju pared an important report giving information as frequenting of public-houses by women and children six county boroughs of Ireland—Dublin, Belfast, Limerick, Londonderry, and Waterford. The obser made by the police were taken from 10 A.M. to 11 except on Saturdays and Sundays, when different h closing obtain, and on these days observation was k while the houses remained open. The results of wh police saw in the way of women and children frequ public-houses are shown in the subjoined table:—

Name of city.		No. of houses observed.		No. of women and child entering.		
				Women.		Child
Dublin	... ...	22	......	46,574	......	27,9
Belfast	... ...	22	......	5,963	......	6,4
Cork ...	... ...	10	......	1,995	......	2,2
Limerick ...	...	6	......	6,493	... ..	4,5
Londonderry	...	8	......	856	......	9
Waterford	...	6	......	5,441	......	2,7

In Belfast the greatest number of cases occurred lowest-class districts. It would appear to be a fairl mon practice for children between seven and 14 ye enter public-houses alone for intoxicating liquor and c home to their parents. The city, the report says, a with spirit groceries, which form a training ground formation of habits which lead to misery and poverty. of the principal causes of the difference between the I and Dublin figures is, according to the Dublin report, t the latter city only one house of the number obser returned as doing grocery business, while in Belfast 22 houses observed 17 do grocery business combine drink and are consequently more frequented by wome Belfast, according to the Belfast report, there are prac no public-houses where groceries are sold. The hous purely for the sale of drink. There is not so much drinking amongst women in Belfast as in Dublin. The about 500 "spirit grocers" and beer retailers in Belfas women order drink in the "spirit groceries," paying fo groceries, and in this way most of the drink taken by v is obtained.

Bacon Curing.

The peculiarly intimate association of pigs, pot poverty, and peasantry of Ireland goes to make the in of "bacon curing" an appealing one on this side c Irish Sea. The bulk of the bacon curing is carried on province of Munster, where some nine large "factorie a capacity for handling about 12,000 to 15,000 amongst them every week" have firmly estab themselves. In such circumstances a specially tive hearing was secured for a lecture delivere March 22nd at Enniscorthy to the North Wexford Fa Society on Bacon Curing and the Dead Meat Trad Mr. Loudon M. Douglas, of the College of Agricu Edinburgh. The lecturer said that while Denmark i twice the size of the province of Munster it has 54 bacon factories which handle as many as 40,000 pigs every week, the whole of the bacon of which was being continuously shipped to the United Kingdom. Much money which is now spent in railway freight and allied expenses would be saved if bacon factories were more numerous in Ireland. The pigs which are produced and grown in so large numbers in County Wexford are, for the most part, sent to Waterford or Limerick, which means that what would be a considerable profit is lost in the process of transfer. The older factories, too, are much more expensive to work than the modern ones, while wanting in the scientific design and construction of the latter. One of the most recently constructed has been aptly described as the "first farmers' bacon factory" in the United Kingdom; it is situated at Roscrea, County Tipperary. The lecturer dwelt on the necessity for a manager of a bacon factory to be conversant not only with the general practice of bacon curing but with its theoretical principles—with the bacteriology of meat, the chemistry of food and of antiseptics and of curing agents, the detection of disease, and many other branches of his important subject—and pointed out that: "It is a curious thing that although the industry represents such a vast amount of money to the country there are no facilities offered either at the agricultural colleges or universities for obtaining technical instruction in these matters. The proper utilisation of the by-products alone might mean increasing the wealth of the country by millions, but there are no facilities offered in Ireland for obtaining the knowledge that would enable any bacon factory managers to carry out the special processes which are so successful in connexion with this business in America and in other countries."

Tuberculosis Exhibition at Bray.

One of the most completely successful of the tuberculosis exhibitions hitherto held in Ireland was that of Tuesday, Wednesday, and Thursday of last week (March 23rd–25th), which was arranged in the Assembly Rooms, Bray, County Wicklow. The work of planning and arranging the hall had been intrusted to the charge of Mrs. Daniel Byrne and the ladies of the Bray Women's National Health Association, and it was admitted by all visitors that the duty had been carried out in the very best way, showing the most careful and effective attention to the requisite classification and order. Lady Aberdeen (accompanied by Lord and Lady Haddo and Mrs. Victor Marshall) motored down from Dublin and arrived at 12.30 o'clock. A magnificent bouquet was presented to Her Excellency and an address was read from the local tuberculosis committee. The latter was acknowledged in a graceful speech, and in another short address Lady Aberdeen declared the exhibition open. Large numbers of visitors attended and examined with attention the models of labourers' cottages, pathological specimens, models of bacilli, statistical charts, geographical maps, &c., which had been amply provided and very judiciously arranged.

Belfast Ophthalmic Hospital.

At the annual meeting of the friends of this charity, held on March 29th, it was reported that there were 106 intern cases and 1450 extern eye, and 759 ear, nose, and throat cases, making a total of 2315 patients. Financially there is a balance against the hospital of £177. Owing to the fact that the committee has been receiving trifling sums from some of the patients, the Commissioner of Valuation has seen fit to place the hospital on the rates of the city on the ground that the hospital makes a private profit by so doing and is not exclusively a charity. A demand has been made for £33 5*s.* for city rates and arrears and for £2 15*s.* for poor rate. These charges have been appealed against, so that the matter is still *sub judice.* It is curious that until last year neither rate nor tax was ever demanded, though no change has been made in the management of the hospital.

March 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Foreign Bodies in the Bronchi Extracted by Superior Bronchoscopy.

AT a meeting of the Hospitals Medical Society held on March 12th M. Guisez gave an account of three cases of foreign bodies in the bronchi. In one case the foreign body—the metal cover of a pencil—was situated in a lower ramification of the bronchus and was particularly difficult to extract. M. Guisez, basing his opinions upon 16 cases which had been under his care, enlarged upon the advantages which the method of superior bronchoscopy possessed over the inferior method. In fact, the latter should only be looked upon as a *pis aller.* M. Guisez added that the diagnosis in these cases was still extremely difficult despite the perfection to which clinical methods had been brought and the aid given by radioscopy.

The Treatment of Exophthalmic Goitre.

At a recent meeting of the Paris Society of Medicine M. Paule Sainton discussed the various treatments of exophthalmic goitre. Exophthalmic goitre is a collection of symptoms (*syndrome*) which react in a different manner to the same agent. In the case of infectious diseases, for instance, some aggravate and some improve, at least temporarily, the symptoms of the disease. It is the same with certain operations, such, for instance, as ovariotomy. In the presence of *this paradoxic reaction of the gland to identical causes* it is difficult to lay down absolute rules as to when one or the other method of treatment should be employed. Out of 19 cases treated by antithyroid hæmo- or sero-therapy M. Sainton noted an improvement in 14, a cure in three, and no result in two. In three cases which were apparently due to infection or to rheumatism sodium salicylate cured one and considerably relieved the other two. In his opinion the most useful tonic was the sulphate of quinine. The results of surgical treatment are very variable. He had seen one cure which had lasted for nine years. His own practice was to reserve surgical measures for very acute cases or for those in which profound cachexia was present.

An Operating Theatre Rated as a Provision Shop.

The following story shows a little expected consequence of an Act of Parliament. The Act of June 28th, 1901, which authorised the city of Lyons to levy sundry taxes in order to make up for the loss which it had sustained owing to the *octroi* having been done away with, contained a certain clause No. 14. This clause laid it down that hotels, inns, *maisons de santé*, or other houses should be assessed at the same rate as shops for the sale of food or drink, because of the dining and other rooms which the visitors enjoyed in common. They also paid inhabited house duty on account of the private rooms allotted to the inmates. The new Surgical Institute of Lyons, which only receives patients needing surgical care, has put in the plea that it should not be taxed at the same rate as an ordinary consulting room, and this is a point of great importance, for inns are rated at 6 per cent. and medical men at 12 per cent. The Conseil d'État has accepted this protest, but the operating theatre has been assessed in a very original manner. In so far as it comes under the head of a room used in common it had been assessed at the same rate as a provision shop, although the patients' private rooms and the private rooms of the medical man in charge paid inhabited house duty, the rule being that a room is assessed differently according to the purpose for which it is used. The Surgical Institute argues that the operating theatre should be considered as a private room for every patient who is operated on, and certainly at first sight it would appear to be a legal pleasantry to assess an operating theatre as a provision shop. But according to clause 14 every place (*local*) must be assessed either as a provision shop or as an inhabited house. The operating theatre cannot be an inhabited house because of the ever-changing succession of patients. Therefore it comes under the other heading.

Epidemic Cerebro-spinal Meningitis.

Epidemic cerebro-spinal meningitis was once a rare disease in France, where it was hardly seen except in military centres, especially those in the East. But for the last few years it has been making steady advances, and cases of it now occur from time to time in civil practice and in places wide apart from each other. On March 9th M. Netter read before the Academy of Medicine a note on a small epidemic which broke out in a suburb of Paris. The disease proved very infectious and in many instances it ended fatally. But very fortunately recourse was made to an antimeningococcic serum of remarkable potency which M. Dopter has been preparing in France and which is the same as Wassermann

Medical News.

UNIVERSITY OF LEEDS.—The following pass-lists have been issued in the Faculty of Medicine:—

FIRST EXAMINATION FOR THE DEGREES OF M.B. AND CH.B, PART. I, *Chemistry and Physics* —C. M. Gozney, H. R. Knowles, M. Peto, H. P. Shackleton, H. A. Sinson, H. W. Symons, H. L. Taylor, C. Ward, and J. Wright.

SECOND EXAMINATION FOR THE DEGREES OF M.B. AND CH.B., PART I. *Anatomy and Physiology.*—A. L. Bastoble, H. Caplan, L. Dunbar, C. J. H. Little, G. E. Macvie, N. V. Milton, F. W. Nunnery, William Robinson, J. B Sinson, J. P. Walker, T. L Walker, F. Wigglesworth, and B. W. F. Wood.

PART II.

Materia Medica and Pharmacy.—H. N. Ingham and C B Richardson. *Diploma in Dental Surgery: Preliminary Examination in Science.*—H. P. Shoesmith.

UNIVERSITY OF GLASGOW.—The following have satisfied the examiners in the fourth (final) professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

John Allan, James George Anderson, William Hunter Stirling Armstrong, Douglas Morris Borland, Morris William Browdy, John Adam Gib Burton, John Cameron, Matthew Ignatius Thornton Cassidy, Weir Burns Cunningham, James Cowie Dick, Alexander Gordon Gilchrist, George Stevenson-Gordon, Edward O'Driscoll Graham, James Harper, M.A.; William Howat, M.A.; John Parlane Kinloch, David Neilson Knox, Alexander Macphail Macdonald, Murdo Duncan Mackenzie, George Macleod, M.A.; Allan M'Pherson, Thomas Marlin, Henry Nimmo Rankin, Alfred Roemmele, William Wilson Rorke, William Rutherford, James Johnston Sinclair, Arthur Turnbull, M.A., B.Sc.; James Brown Whitfield, John Alexander Wilson.

The following passed with distinction in the subjects indicated:—

In (*a*) Surgery and Clinical Surgery, (*b*) Practice of Medicine and Clinical Medicine, (*c*) Midwifery. George Macleod, M.A. In (*a*) Surgery and Clinical Surgery, (*b*) Midwifery: William Howat, M A; William Rutherford, and Alexander Stewart. In Surgery and Clinical Surgery: Winifred Margaret Ross, James Johnston Sinclair, and Arthur Turnbull, M.A., B.Sc. In Midwifery: Matthew Ignatius Thornton Cassidy, John Parlane Kinloch, Robert Charles Robertson, and William Wilson Rorke.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.—PART II.

Midwifery.—Thomas A. Hughes, Douglas M. Moffatt, Cecil P. Smyly, Henry R. Kenny, William P. H. Smiley, Desmond Drew, Joseph P. R. Poch, Brindley H. Moore, Wellesley R. Allen, Charles G. S. Baronsfeather, Peter H. Lemass, Denis J. Stokes, Wallace D. Mitchell, Hugh S. Metcalfe, and Joseph E. N. Ryan.

INTERMEDIATE MEDICAL EXAMINATION.—PART I.

Arthur Chance, Frank Crosbie, Oswald C. S. Tandy, Gerald G. P. Beckett, Hubert G. Holdbrook, William A. Taylor, Samuel A. Lane, Ronald G. M'Entire, Leonard Shiel, and James C. Kelly.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* The number of diplomas granted here in the year 1907–08 was 827; in the four previous years the numbers were 1057, 729, 845, and 553.—*Beyrout* (*French Faculty of Medicine and Pharmacy*)*:* The chair of Clinical Surgery and Pathology, which was vacated last summer by the resignation of M. Hache, has not yet been filled up. This faculty enjoys the power of granting the French State diploma of Doctor of Medicine, which confers the right to practise throughout the Ottoman Empire and also in all the territories of the French Republic. The course and examinations are similar to those of the universities in France, though some of the professors and examiners are appointed by the Turkish Government. All Orientals are admitted as students, also Europeans whose families are permanently settled in the East. Last year the total number of students was 172, of whom 30 received the doctorate.—*Cincinnati* (*Miami Medical College*)*:* Dr. Walter E. Murphy has been appointed Assistant Professor of Laryngology and Otology.—*Nantes*: Dr. Col has been appointed to the chair of Materia Medica in succession to M. Ménier.—*New Orleans* (*Tulane University*)*:* Dr. Oliver L. Pothier has been appointed Assistant Professor of Pathological Anatomy.—*Odessa:* Dr. V. Philamoff has been recognised as *privat-docent* of Ophthalmology.—*Rome:* Dr. Tommaso Mancioli has been recognised as *privat-docent* of Otology and Laryngology.—*St. Petersburg* (*Military Medical Academy*)*:* Dr. K. J. Povarnin has been recognised as *privat-docent* of Neurology and Psychiatry.—*Tubingen:* The title of Extraordinary Professor has been conferred upon Dr. Blauel, *privat-docent* of Surgery; Dr. Brunn, *privat-docent* of Surgery; and Dr. Linser, *privat-docent* of Dermatology.—*Vienna:* The title of Extraordinary Professor has been conferred upon Dr. Karl Sternberg, *privat-docent* of Pathological Anatomy; Dr. Heinrich Peham, *privat-docent* of Midwifery and Gynæcology; and Dr. Leopold Réthi, *privat-docent* of Laryngology.

MIDWIVES ACT COMMITTEE.—The ninth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on Wednesday, Mr. Almeric FitzRoy, the Clerk of the Council, presiding. The following witnesses attended and gave evidence: Sir Shirley F. Murphy, medical officer of health of the County of London, on behalf of the London County Council; Mrs Swinton, matron of the Buckingham Palace-road workhouse of the St. George's (Hanover-square) Union, on behalf of the National Association of Workhouse Masters and Matrons; and Mr. Edward Sergeant, county medical officer of health, Lancashire, on behalf of the Incorporated Society of Medical Officers of Health and on behalf of the Midwives Act committee of the Lancashire county council.

EAST-END MOTHERS' LYING-IN HOME.—The annual meeting of this institution was held on March 24th at the Home, Commercial-road, E., when Mr. Alfred Owen Lankester presided. The medical report stated that during the year 1908 498 women were delivered, 491 children being born alive and 12 stillborn. Five died and there were five sets of twins. Of the out-patients 708 were delivered, 702 children being born alive and 16 stillborn. Three died and there were ten sets of twins. Mr. M. Cursham Corner, honorary visiting medical officer and lecturer, in concluding his report says: "1908 has been not inaptly called the Children's Year. Its influence may bring about better parental conditions, as well as improved surroundings, both before and after birth. The commonest causes of infantile mortality are poverty, ignorance, and neglect, and the predominating one in the East-end is poverty." He also called attention to the remarkable fact that no maternal death occurred in connexion with the work of the institution during the year. Financial help is greatly needed for this deserving institution.

THE LONDON FIRE BRIGADE.—The report of the Fire Brigade Committee of the London County Council submitting the report of the chief officer of the Fire Brigade, Captain J. de C. Hamilton, for the year 1908 has recently been published. The number of deaths by fire was the same as in 1907—viz., 93; of these victims 66 were injured and removed before the brigade was called, and of the remaining 27, 10 were taken from the buildings by firemen, but succumbed afterwards. It is the custom of the report to include all deaths from fire in the county of London, whether the brigade was called to deal with the outbreak which occasioned them or not. The 93 lives were lost in 84 separate fires and 53 of the fatalities concerned children under 12 years of age. These were in 31 cases due to the victims playing with fire or matches; mineral oil was responsible for 7; 10 were caused by clothing coming into contact with oil or gas stoves; and 10 by sparks from fires. The practice of leaving young children in rooms where unguarded fires are burning is rightly reprehended and the report points out that under the Children Act, 1908, which comes into force on April 1st, this form of carelessness will be made a penal offence if it result in serious injury to the child. Attention is also drawn to the fact that considerable danger is incurred in following the advice given in certain newspapers regarding the use of petroleum as a cleansing agent. Amongst the statistics given we note that the brigade attended 3238 fires, excluding 791 chimney fires, during 1908, and of this number 61 were reported as "serious." The chief officer of the brigade regrets that many new buildings are being erected in which unprotected constructional ironwork is used, and also that the valuable properties of fire-resisting glass have not received wider appreciation. In referring to notable fires of the year the report notes that 2500 feet of hose had to be coupled up to reach the seat of fire near the Moorgate-street Station on the occasion of the outbreak on the City and South London Railway. We are glad to learn that improvement has been made in the metropolitan water-supply available for brigade purposes, and that a radical improvement is being effected in the *fire-alarm system, involving improved telephone facilities* for calling the brigade. The chief officer lays it down that a knowledge of the position of the nearest fire-alarm or fire station is the duty of every citizen. Perhaps the most interesting part of the report is that dealing with the employment of motor traction for brigade purposes, which is being gradually extended with such good results that future stations erected will be entirely motor stations. There are at present three with complete motor equipment, which includes *altogether six steam motor fire-engines, five* petrol motor tenders (including one first-aid motor), six petrol motor-escape vans, and four service motor-cars. Horsed appliances have, of course, done splendid work in the past, but the advantages of motor traction are so apparent that we *are glad to see the* brigade does not intend to adopt a conservative policy in the matter.

OPHTHALMOLOGY AT OXFORD.—The sixth annual post-graduate course on ophthalmology in connexion with the Faculty of Medicine of the University of Oxford has been arranged from July 5th to 17th. The main idea of the course is to demonstrate (in actual patients as far as possible) the whole range of *ophthalmology, in order to make the reading of a text-book* more profitable than can be the case when relying merely on pictures. The first part of the course will be mainly devoted to demonstrating the practical examination of eye patients, the use of the ophthalmoscope, and the work of refraction. During the second part the work will be more specialised and lectures will be delivered by various ophthalmic surgeons. As well as the mere routine cases, there will be a large selection of patients of unusual interest for the benefit of those who are more experienced in eye work. Altogether some 500 cases will be present for demonstration. The course will be illustrated by the lantern. The fee for the course is £5 5*s.* Medical men attending the course will be provided with board and residence at Keble College at the rate of 7*s.* 6*d.* a day during the second week, but during the first week lodgings must be secured. Further particulars can be obtained from Mr. Robert W. Doyne, Margaret Ogilvie's reader in ophthalmology in the University of Oxford, 30, Cavendish-square, London, W.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the list of prizes awarded for the winter session, 1908–09:—Descriptive anatomy: Junior: W. I. Adams, first prize (£2) and medal; G. E. Pepper, second *prize (£1) and certificate. Senior: M. J. Hillery, first* prize (£2) and medal; I. M. Swanepoel, second prize (£1) and certificate. Practical anatomy: First year: G. E. Pepper, first prize (£2) and medal; H. A. S. Deane, second prize (£1) and certificate. Second year: A. G. Mosbery, first prize (£2) and medal; I. M. Swanepoel, second prize (£1) and certificate. Practice of medicine: W. V. Johnston, first prize (£2) and medal; J. S. Pegum, second prize (£1) and certificate. Surgery: J. S. Pegum, first prize (£2) and medal. Midwifery: F. W. Warren, *first prize (£2) and* medal; J. S. Pegum, second prize (£1) and certificate. Physiology: S. Griffin, first prize (£2) and medal; M. J. Hillery, second prize (£1) and certificate. Chemistry: J. C. Sproule, first prize (£2) and medal; B. Goldberg, [illegible] ncan, [illegible] (£1) [illegible]) and [illegible] The lectures and *practical courses of* the summer session commenced on Thursday, April 1st.

THE PUBLIC MEDICAL SERVICE AT HAMPSTEAD.—On March 30th, at the Hampstead Conservatoire, a meeting of the local profession was held, under the auspices of the Hampstead Division of the British Medical Association, to consider proposals for the establishment of a public medical service in Hampstead, in order to provide for uniformity in contract practice and for the treatment of poor school children under the new Medical Inspection Act. In proposing the first motion,

> That it is desirable that a Public Medical Service be formed in Hampstead and neighbourhood for the organisation and provision of medical attendance for persons unable to pay the ordinary medical *charges in the usual manner,*

Mr. C. W. Cunnington laid stress on the many ways in which lay bodies threaten to curtail general practice, and advocated medical organisation to meet those dangers. Dr. J. Ford Anderson, in seconding, enlarged on the abuses of contract *practice.* The motion was carried unanimously. Dr. H. J. Macevoy *proposed the second motion*—

> That this meeting appoint an organising committee to draw up rules for the proposed service, to recommend names for its officers and committee, and to secure the adhesion of the medical practitioners in Hampstead and the neighbourhood to the service,

and expressed a hope that the service would federate all the various [illegible] Mr. W. [illegible] unanim[illegible] appointed to serve on the organising committee: Dr. Ford Anderson, Mr. S. L. Archer, Dr. L. Barnett, Mr. Cunnington, Dr. Percy C. Evans, Dr. W. Winslow Hall, Dr. Macevoy, Dr. Picard, Dr. G. D. Pidcock, and Mr. A. R. Roche.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Ambulance Service in the Metropolis

THE Departmental Committee on the ambulance service in the metropolis has presented a report condemning the existing arrangements as insufficient and defective. (The report is dealt with at length in another column.)

Medical Acts Amendment Bill.

Mr. COOPER has presented a Bill in the House of Commons designed "to regulate the administration of anæsthetics, to make regulation relative thereto, and to amend the Medical Acts." He has given it the name of the Medical Acts Amendment Bill. It has been read a first time. In introducing the Bill Mr. COOPER has the support of Sir WALTER FOSTER, Sir WILLIAM COLLINS, Sir JOHN BENN, Mr. ACLAND ALLEN, Mr. BARNES, Dr. RUTHERFORD, Mr. BERTRAM STRAUS, and Mr. CARR-GOMM. The text of the Bill is not yet issued. However, its principal terms have transpired. The first clause of the Bill requires that after Jan. 1st, 1911, no person shall be registered by the General Medical Council unless he submits satisfactory evidence that he has been instructed in the administration of anæsthetics. After that date it is proposed that no person except a registered medical practitioner may give any vapour, gas, or drug, solid *or liquid,* with the object of producing unconsciousness during any operation, examination, or childbirth. The penalty is £10 for a first *offence and £20 for a second.* A proviso is introduced to deal with cases of urgency or cases under the supervision of a registered medical practitioner. A power is given to the General Medical Council *to make orders and regulations. Further, the subject of giving* certificates of death in the case of persons dying under an anæsthetic is dealt with. The Bill also takes cognisance of dentists, and it is proposed to allow persons already registered under the Dental Act at the time when the Bill takes effect still to enjoy the right to give an anæsthetic for a dental *operation.*

The Royal Commission on Tuberculosis.

It is expected that the work of the Royal Commission on Tuberculosis will come to a close within the financial year 1909–10. It was appointed *in August, 1901, and has issued three interim reports.* The estimates set apart £3939 for the expenses of the Commission this year. Of this sum £3050 are to be devoted to scientific investigations. During the financial year 1908–09 the vote for the Commission amounted to £5491, of which £4582 went *to the expense of scientific investigations.*

The Oaths Bill.

The Oaths Bill, which is designed to substitute as far as possible the taking of the oath with uplifted hand for the practice of "kissing the Book," is making rapid progress. It has emerged from a Standing Committee of the House of *Commons in a stronger form.* If no further change is introduced into it the judge or magistrate will administer the oath with uplifted hand in all cases except when the witness asks to be sworn in some other fashion.

Registration of Nurses (Scotland) Bill.

Mr. CLEL[illegible] establish an [illegible] Scotland." [illegible] now before the House of Commons

HOUSE OF COMMONS.

WEDNESDAY, MARCH 24TH.

Legislation on Tuberculosis.

Mr. HUDSON asked the [illegible] whether it was his inte[illegible] bovine tuberculosis is at present receiving my attention in connexion with the Milk Bill which I propose to introduce. As regards human tuberculosis, I do not at the moment contemplate legislation on the subject. I have recently issued an Order providing for the compulsory notification of pulmonary tuberculosis when occurring amongst persons in Poor-law institutions or under the care of Poor-law medical officers; and this Order has, I am glad to find, stimulated voluntary notification of the disease when occurring among other persons in the large number of districts where a system for that purpose is in force. I shall by no means lose sight of the matter, but I think that developments with regard to it must be gradual.

THURSDAY, MARCH 25TH.

Small-pox at Bristol.

Mr. CAVE asked the President of the Local Government Board whether an outbreak of small-pox had occurred in Bristol; whether, in spite of the advice of the Board's inspector, the board of guardians refused to make special arrangements for the vaccination of unvaccinated children and for revaccination; whether, on the Local Government Board themselves instructing the vaccination officer to provide special facilities, the health committee refused to permit the issue by their medical officer of bills notifying the names of the vaccinators and the places where they would attend for vaccinations; how many cases of small-pox had already occurred in the city and how many had proved fatal; and what steps the Local Government Board proposed to take in the matter.—Mr. BURNS replied: The answer to the first two points in the question is in the affirmative. I have caused one of the medical officers of the Local Government Board to pay two visits to Bristol and the neighbourhood owing to the outbreak, and he has conferred with the authorities and officers concerned as to the precautions which should be adopted, and various measures have been taken accordingly.

The Milk-supply in France and Germany.

Mr. LEWIS HASLAM asked the President of the Board of Trade whether his attention had been called to the fact, as stated in the *Board of Trade Labour Gazette* for March, that the retail price for milk in urban centres was, when the investigation was made in October, 1905, 25 per cent. cheaper in Germany and 30 per cent. cheaper in France than in England; would he state whether the relative cheapness in those countries was due to municipal or Government action; and would he state, or take means to endeavour to ascertain, why milk was practically the only exception to the rule that the principal articles consumed by the working classes in this country were much cheaper than in France or Germany.—Mr. CHURCHILL furnished the following written answer: The relative cheapness of milk in France and Germany appears to be due, not to municipal or Government action, but to greater scale of production and smaller cost of distribution. The scale of production is larger both in France and Germany, the number of cows kept being 18 per 100 of the population in Germany and 19 in France, as against 10 per 100 in the United Kingdom. The distance which milk has to be brought to the house is, as a rule, not so great as in this country, and the milk is commonly distributed to the consumer by means of barrows drawn by dogs and led by women and not, as in this country, by means of carts drawn by horses and driven by men.

The Sanitary Condition of Seamen's Sleeping Quarters.

Mr. LEWIS HASLAM asked the President of the Board of Trade whether his attention had been called to the report of Dr. J. Howard-Jones, medical officer of health of Newport (Mon.), in which he called attention to the offensive and insanitary condition of the seamen's sleeping quarters and other accommodation in many ships, some of which were new; and whether he would cause a thorough investigation to be made by the officers of the Board of Trade, with the view of inforcing the adoption of proper sanitary conditions on such ships.—Mr. CHURCHILL wrote in reply: On the receipt of this report in October last the Board of Trade at once made inquiries into the particular case referred to by the medical officer, and the defects which had been observed were made good. Similar action is always taken when particular cases are reported by the local sanitary authorities.

TUESDAY, MARCH 30TH.

Glycerinated Calf Lymph in Ireland.

Answering Mr. LUPTON, Mr. BIRRELL said: The Local Government Board for Ireland inform me that the glycerinated calf lymph procured by them under contract from the National Calf Vaccine Institute, Sandymount, Dublin, is, before issue from the Board's vaccine department, tested as to its efficiency and subjected to careful bacteriological examination. Its purity is thus insured. The dispensary medical officers throughout the country being aware of these arrangements to secure proper lymph, a further certificate of purity appears to the Board to be unnecessary.

WEDNESDAY, MARCH 31ST.

Aliens and Trachoma.

Mr. RUPERT GUINNESS asked the Secretary of State for the Home Department whether his attention had been drawn to the number of newly arrived aliens who presented themselves at the Royal London Ophthalmic Hospital for treatment for long-standing trachoma, and to the fact that as many as 90 per cent. of the sufferers from this disease during the six months with which the last report of the hospital dealt were aliens, and to the chairman's recommendation that aliens who had contracted this disease should be prevented from landing in this country; and whether, in view of the fact that this disease was being introduced into this country on an extensive scale by aliens who had not submitted themselves to an inspection at an immigration port, he would consider the expediency of lowering the number of alien immigrants who could be carried in a non-immigrant ship at all events as concerned vessels bringing aliens to the port of London.—Mr. GLADSTONE replied: I understand that the statement mentioned in the first part of the question was made by the chairman of the Royal London Ophthalmic Hospital at the recent annual general meeting of the governors. Without altogether accepting as correct the further statement made by the honourable Member, I may say that I am asking for further and more exact information as regards the general statements contained in the question.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOSTOCK, A. H., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer for the Oving and Boxgrove Districts of the Westhampnett Union, Chichester.

MANSON, J. S., M.B., Ch.B. Edin., has been appointed Honorary Assistant Surgeon to the Warrington Infirmary.

MILNE, LINDSAY S., M.B., Ch.B. Edin., has been appointed First Assistant in the Russell Sage Institute for Pathology, New York, U.S.A.

[illegible] land.

ROSE, WILLIAM, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Consulting Surgeon to the British Hospital for Mental Disorders [illegible]

WORGER, THOMAS HEWLETT, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Radstock (Somerset) Urban Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALL SAINTS HOSPITAL FOR OUT-PATIENTS, Buxton-street, E.—Honorary Medical Officer for Monday afternoons.

BARKING TOWN URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary £365 per annum.

BARNSLEY, BECKETT HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

BIRKENHEAD UNION INFIRMARY AND SANATORIUM.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Also Resident Surgical Officer. Salary in each case £80 per annum, with board, washing, and attendance.

BIRMINGHAM, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100 per annum.

BRISTOL, BRISLINGTON HOUSE PRIVATE ASYLUM.—Senior Resident Physician.

BRISTOL GENERAL HOSPITAL.—House Physician, Casualty House [illegible] sician for six months. Salary [illegible] —Resident Medical Officer, un- [illegible] with apartments, attendance, &c.

BROWN ANIMAL SANATORY INSTITUTION.—Superintendent. Salary £300 per annum.

CANCER HOSPITAL, Fulham-road, London, S.W.—Surgical Registrar, *Salary £26 5s. per annum.*

CANTERBURY BOROUGH ASYLUM.—Locum Tenens Assistant Medical Officer. Salary 3 guineas a week, with board, lodging, laundry, and attendance.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, [illegible] per annum, with board and residence.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 [illegible] and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon; also Assistant Casualty Medical Officer; both unmarried, for six months. Salary in each case £30, with board and residence.

LANARK MIDDLE WARD ISOLATION HOSPITAL, near Motherwell.—[illegible] Salary £100 per annum.

LIVERPOOL INFIRMARY FOR CHILDREN.—Resident Medical Officer for six months. Salary £30, with board and lodging.

[illegible] rgeon. Also Two [illegible] per annum, and of [illegible] Surgeon. Salary [illegible] Superintendent. Salary £425 per annum.

MANCHESTER WORKHOUSE, Crumpsall.—Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, washing, and attendance.

MARGATE, ROYAL SEA BATHING HOSPITAL.—*Honorary Assistant Visiting Surgeon.* Also Resident Surgeon as Junior and Senior. Salary of the two offices at rate of £80 and £120 per annum respectively, with board and residence.

METROPOLITAN BOROUGH OF ST. MARYLEBONE.—Medical Officer of Health. Salary £600 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE [illegible] geon for six months. Salary £20, with board, lodging, and washing.

OLDHAM INFIRMARY.—Junior House Surgeon. Salary £75 per annum, with board, residence, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary in each case at rate of 50 guineas per annum, with board and residence.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

RAINHILL, NEAR LIVERPOOL, COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

[illegible] missions.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Physician. Also Honorary Anæsthetist.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

SOUTHPORT EDUCATION DEPARTMENT.—School Medical Officer. Salary £250 per annum.

[illegible] geon, with [illegible] Salary [illegible]

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant [illegible] Salary at rate of £50 per annum.

[illegible] FOR CONSUMPTION.—Assistant [illegible] ed. Salary £100 per annum.

[illegible] te street, Chelsea, S.W.—House [illegible] and lodging.

WA[illegible] urgeon, unmarried [illegible] washing.

WA[illegible] HOSPITAL.—House [illegible], with apartments, board, and service.

Births, Marriages, and Deaths.

BIRTHS

[illegible] a son.

[illegible] road, Wimbledon, [illegible] ay, B.A., M.B. [illegible] Ayr, the wife of [illegible] rviving only 36 hours.

PALIN.—On March 26th, at The Oaks, Fakenham, Norfolk, the wife of Edward W. Palin, M.A., M.B. Oxon., M.R.C.S., L.R.C.P., of a daughter.

SCOTT.—On March 31st, at 46, Queen Anne street, Cavendish-square, W., the wife of Sydney R. Scott, M.S. Lond., F.R.C.S. Eng., of a son.

SPITTA.—On March 24th, at Wimbledon, S.W., the wife of Harold Spitta, M.D., of a son.

DEATHS.

BLAIKIE SMITH.—On March 24th, at Villa Victoria, San Remo, Patrick Blaikie Smith, M.D., late of Aberdeen.

[illegible] Lodge, Worthing, Augustus [illegible], L.S.A., Senior Surgeon [illegible] Gervis, M.D., M.R.C.S., [illegible]

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE RATE OF COOLING OF VARIOUS POULTICES.

DURING the last few years the idea has gained ground that the old-fashioned bread and linseed poultices do not retain their heat so long as poultices of the cataplasma kaolini type, made from kaolin and glycerine. But it would appear, from experiments made by Dr. J. D. Pilcher in the Pharmacological Laboratory of the Western Reserve University (*Journal of the American Medical Association*, March 6th), that this idea is baseless. A comparison of the rates of cooling of several poultices showed that a linseed poultice cools slightly more slowly than a kaolin poultice. During the first 20 minutes, down to 75° C., the temperatures ran fairly parallel, and then the temperature of the linseed poultice remained about 5° C. above that of the kaolin poultice until the close of the experiment. Dr. Pilcher found that oatmeal, bread, and corn-meal poultices apparently retain their heat even somewhat better than the linseed poultice; the curves show a difference of from two to eight degrees between the temperatures of these masses and kaolin poultice. In order to determine the reason for the rapid cooling of the latter, experiments were made comparing its rate of cooling with that of its chief constituents. It was observed that dry kaolin cools more quickly than the kaolin poultice, while glycerine cools much more slowly. The temperature curves of glycerine and linseed poultice are practically the same. It was also found that water cools at about the same rate as kaolin poultice, while soft paraffin cools rather more quickly. These experiments are of great practical value, since they demonstrate the superiority of the time-honoured and cheap linseed or bread poultice over the much more expensive kaolin poultice. In cases where it is required to cover large areas the price of the latter becomes prohibitive for poor patients, whereas they are able to purchase for a few pence sufficient crushed linseed to cover a large area with a poultice of considerable thickness.

A SIMPLE EXPEDIENT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 6th I notice a reference to a "clip attachment" for preventing clinical thermometers falling out of the pocket when one stoops. This useful article has come too late for me, however, who have for many years used a device as simple and inexpensive as it is efficient, and which is already in the possession of every medical practitioner and can be applied in a few seconds. Having broken many clinical thermometers in stooping—e.g., to inflate cycle tyres—I thought of a fountain-pen clip, but rejected it as only adding to the many contents of one's pockets, and bethought myself of the admirable non-slipping qualities of rubber. I found that by twisting a small thin rubber band several times around the thermometer case or fountain-pen it was impossible for such an article to fall out of the pocket, and I cordially recommend this simple device to all in need of it. My only fear is that it will not meet with the approval of makers of clinical thermometers, whose output its adoption will certainly restrict.

I am, Sir, yours faithfully,

Driffield, East Yorks, March 29th, 1909. A. T. BRAND, M.D. Aberd.

AN ENEMA SYRINGE AS A FIRE EXTINGUISHER.

"M. W. G." sends us an account of an exciting experience which she had recently whilst nursing a confinement case in the South of England, and in which the situation appears to have been saved by her prompt action. The case was in an old house, and one morning a large oak beam in the chimney of the patient's room, about four feet above the grate, caught fire. No obvious means of extinguishing it being at hand, "M. W. G." bethought herself of her Higginson's enema syringe, and standing a jug of water in the grate she used the syringe to play upon the blazing beam for nearly an hour with such effect that the fire was extinguished. Her patient fortunately slept through the occurrence. It was found next morning that the beam had been burnt in 3 feet of its length and 6 inches of its depth, so there is every reason to think that the house owes its security to the nurse's resourcefulness and hard work. We congratulate "M. W. G." on the happy issue, the more especially as we know of a previous instance in which the same device was applied unsuccessfully on the occasion of a fire low down in the chimney of a ward in a south coast hospital. On that occasion the patients by no means slept through it all, for pailfuls of water had to be thrown up the chimney, and by the time the fire was extinguished the ward was in a state of partial flood, and a heated discussion was proceeding between the house surgeon and the local constabulary as to whether the fire brigade should or should not be summoned.

MEDICAL GOSSIP FROM 1847.

A CORRESPONDENT sends us the following extracts from the *Illustrated London News* of March 13th, 1847, commenting upon the perfection of anæsthesia at so early a date. The description of the patient's conduct is certainly interesting but hardly seems consistent with a very complete anæsthesia. "A considerable portion of the lower jaw-bone of a person named Riley was removed at the Devonport Workhouse a few days ago without the slightest pain, the patient being under the influence of ether. He smiled and talked while the parts were being dissected." Our correspondent adds Lower in the same column is this paragraph:—"At the last returns the Income Tax Act no fewer than 30 surgeons practising in London admitted that their professional earnings amounted to £10,000 per annum each, and of these three were upwards of £20,000 each" It would be interesting to know how this compares with the returns for last year.

THE AERIAL LEAGUE.

A MEETING of the Aerial League of the British Empire is to be held at the Mansion House on April 5th at 3 P.M., the Lord Mayor presiding. The league is a non-political organisation and its object is stated to be "to secure and maintain for the Empire the same supremacy in the air as it now enjoys on the sea." The league wishes to bring home to the minds of the inhabitants of the Empire in general and of London in particular that while other countries are spending enormous sums of money for the encouragement of "aviation" England is doing practically nothing. A preliminary meeting was held at the Carlton Hotel on Feb. 21st, which made it plain that there is a large amount of interest taken in the matter by people of all classes, which only wants organising in order to become a focus for a national movement. With the many political problems which aerial locomotion may bring to a head we as medical journalists have nothing to do. But when flying becomes as common a mode of locomotion as other forms of travel are now, there will be many problems in connexion with the transmission of epidemic diseases, such as cholera and plague, which will demand the closest attention from those whose duty it is to protect their countries from possible invasion by such disease.

A CORRECTION.

THE Dusmo Company, Limited, of West Ham-lane, Stratford, E., point out that in our analytical notice of their dustless sweeping powders last week the name "Lyndus" applied to one of them should have been written *Lydus*.

◆

K. R.—We are making inquiry into the matter.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. Charles Cameron): at 4.30 P.M.

Papers:

Dr. Gordon Sharp: Experiments and Experiences with the Heart Tonics—Pharmacological and Clinical.

Dr. William Bain: The Action of Digestive Ferments upon Each Other.

PATHOLOGICAL SECTION (Hon. Secretaries—Leonard S. Dudgeon, O. Grünbaum) at the National Hospital, Queen-square, W.C: at 8.30 P.M.

Dr. F. W. Mott, F.R.S., and Dr. Edgar Schuster: The Examination of the Brain from a Case of Death by Electric Shock.

Dr. E. F. Buzzard and Dr. G. M. Holmes: The Post-mortem [illegible] of Six Cases of Myasthenia Gravis.

[illegible] of the Upper Motor Neurones

[illegible] ions of the Oculo-motor Nuclei [illegible] th Bilateral Ophthalmoplegia.

Card Specimens:

Dr. G. Sutherland: Post-Mortem Specimens from a Case of Myasthenia Gravis.

Dr. S. A. K. Wilson: Specimens from a Case of Myasthenia Gravis.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who m[illegible] supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

The Goulstonian Lectures

ON

SOME DISORDERS OF THE CEREBRAL CIRCULATION AND THEIR CLINICAL MANIFESTATIONS.

Delivered before the Royal College of Physicians of London on March 11th, 16th, and 18th, 1909,

BY ALFRED E. RUSSELL, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

LECTURE II.[1]

Delivered on March 16th.

THE CORRELATION BETWEEN THE CIRCULATORY CHANGES POSTULATED AS THE PRECIPITATING FACTOR IN THE EPILEPTIC FIT AND THE VARIOUS SYMPTOMS OF, AND THE RECOVERY FROM, THE ATTACK.

MR. PRESIDENT AND GENTLEMEN,—For any theory of the mechanism of the epileptic fit to rest on a sound basis, it is necessary that it should offer a reasonable explanation of, or at least not be inconsistent with, the various manifestations observed in the attacks. It is submitted that the circulatory failure here postulated *does offer a more reasonable* explanation than any hypothesis yet brought forward.

1. *The aura.*—Francis Hare maintains that the explanation of the aura is to be sought in the peripheral vaso-constriction which he postulates as preceding the cardiac inhibition. That a partial cerebral anæmia is capable of giving rise to the phenomena of an epileptic aura has been demonstrated experimentally by Leonard Hill,[2] who says: "I myself have twice produced clonic spasms in myself by compression of one carotid. The first effect on applying the compression was a *sensation in the eye on the same side; then there followed a sensory march of formication down the opposite side of the body. This began in the fingers, spread up the arm, then down the leg.* Finally clonic spasms of the hand occurred, accompanied by an intense feeling of vertigo and alarm."

The association of epilepsy with migraine is well known, and in a unique case recorded by Gowers of a girl who was subject to both migraine and epilepsy, the visual aura preceding the migraine was on one occasion followed by an epileptic fit.

Some of the prolonged symptoms in the more abnormal faints are obviously vaso-motor or cardiac in origin, and yet were they of momentary duration they would be typical epileptic auræ. Or, as Gowers puts it, in discussing one case with attacks of cardiac and respiratory distress: "Symptoms usually momentary, as the aura of epilepsy, become protracted, extended, as it were, into a vagal attack."

2. *Unconsciousness.*—In the absence of an aura (and it is noteworthy that it is frequently absent) the first feature in an epileptic fit is sudden loss of consciousness. So sudden may it be that the patient falls with the utmost violence. Current views on the pathology of epilepsy afford no satisfactory explanation of this. Yet so dramatic a feature should be susceptible of some simple explanation. The loss of consciousness is not caused by the convulsions. It precedes them in point of time, and in tetanus and strychnine poisoning the spasms may be every whit as severe as those of idiopathic epilepsy, but are not attended with unconsciousness. Now one of the most obvious causes, if not almost the only one, of sudden unconsciousness (excluding severe cranial injuries) is a sudden interference with the flow of blood to the brain.

The phenomena of the epileptic fit are commonly explained as being the result of an intense discharge from the cortical grey matter. On the motor side this discharge leads to severe muscular spasms, to excess of disordered function. As regards consciousness, this is absolutely and suddenly lost. I cannot understand how this can be caused by a discharge. It seems to me that the very opposite factor—viz., cessation of activity—must be involved. Consciousness is, I think, too commonly regarded as too mysterious to be governed by ordinary physiological processes, but the brain is certainly very tenacious of this attribute and a symptom so extraordinarily dramatic and serious as sudden unconsciousness demands an explanation. Save for conditions associated with the vascular system, such as cerebral embolism, stoppage of the heart, sudden faint, &c., sudden unconsciousness is an almost unknown event. But with a *sudden cessation (or extreme enfeeblement) of the whole cerebral circulation* unconsciousness *must* occur. The phenomena of heart block show that, in proportion as the period of cardiac asystole increases, we have varying degrees of cerebral failure, transient unconsciousness indistinguishable from that of *petit mal*, attacks with very transient spasm, and, finally, definite epileptic fits. Inasmuch as it has been shown that in some cases of idiopathic epilepsy cardiac inhibition does occur and precedes the onset of the fit it is difficult to avoid the conclusion that the unconsciousness and the fit are the direct results of the cardiac inhibition.

3. *Convulsions.*—The classical experiments of Kussmaul and Tenner prove the intimate relationship existing between a sudden cerebral anæmia and the production of convulsions. Their experiments were, moreover, not masked by the administration of anæsthetics. It is also well known that severe hæmorrhage in man can give rise to the most typical epileptic fit.

(*a*) *The mechanism of tonic spasm.*—This is a problem of great difficulty. Spasticity of muscles is observed in lesions affecting the pyramidal tract, and is accounted for by over-action of the spinal cord when the inhibitory influence of the brain is removed. In an epileptic fit tonic spasm appears with great suddenness. On the hypothesis of a sudden failure of the cerebral circulation it might be attributed to a removal of the inhibition influence of the brain (possibly allied to the decerebrate rigidity described by Sherrington in animals with transection of fore-brain). It is well known that sudden death may occur during puncture of lung for suspected pleural effusion and during the washing out of empyema cavities. In a paper published by the author on this subject[3] the insertion of the exploring needle was immediately followed in one case by death from cardiac failure, and the point of interest in this connexion is that it was accompanied by tonic extensor spasm of arms and convergent squint. The condition of the legs was not observed, but it is probable that they shared in the spasm. Similarly, tonic spasm occurred in two cases recorded by Cayley and by Vallin in which cardiac inhibition occurred during pleural lavage. It occurs frequently on experimental ligation of the cerebral arteries in animals. These facts *support the view that the tonic spasm of the epileptic fit is* due to sudden cerebral anæmia.

(*b*) *Clonic spasms.*—In the case of sudden death above recorded after exploratory puncture of lung only tonic spasm was observed. The change from tonic to clonic spasms in an ordinary epileptic fit is of great interest. Long Fox,[4] who attributed the loss of consciousness and the tonic spasm to cerebral vaso-constriction, ascribed the clonic convulsion to a "gradual yielding of the vaso-motor constriction, allowing at first more blood to enter the arteries than during the period of tonic spasm, but yet far less than is necessary for controlled movement or for rest." In this connexion a case recorded by Walter Broadbent[5] is of great importance.

The patient was a woman, an epileptic, aged 44 years, who had suffered from rheumatic fever in childhood and showed symptoms of cardiac disease One evening, when talking to her daughter, she suddenly became unable to speak plainly and became rigid. The daughter stated that, instead of the usual fit, there was irregular jerking confined to the right arm and leg The left arm and leg remained absolutely passive She passed urine in the fit. She was unconscious for five days after the fit She then showed complete left hemiplegia, hemianæsthesia, and hemianalgesia. Death occurred on the ninth day. Post-mortem, in the right middle cerebral artery, just beyond the point of origin, a small embolus was found with a
distal thrombus for
vessel was softened
surrounding parts,
state of extreme softening

The importance of this case lies in the fact that the patient was the subject of epilepsy. It is presumable that the embolus gave rise to a fit in a subject prone to epilepsy, but the fit was represented by right-sided spasms only. The left side remained absolutely passive and the embolus in the right middle cerebral artery would prevent the return of blood to the right half of the brain after the cardiac inhibition was passing away.

4. *The physiological mechanism underlying recovery from an epileptic fit.*—Whatever be the immediate factor precipitating an epileptic fit, it is one which is very transient in its action and speedily recovered from. It is one, moreover, which is obviously capable of being brought into action repeatedly. In epilepsy of long duration the patient exhibits a very marked mental degradation, but the effect produced by each fit is imperceptible. Quite apart from the effect produced on the brain by the repeated attacks of cerebral anæmia here postulated as the essential factor of the fit, the intense venous engorgement resulting from the convulsive movements and the asphyxial character of the blood would presumably inflict considerable damage on the brain substance, damage, moreover, repeated over and over again. It would not appear unreasonable to assume that the slight morbid changes described in the brains of epileptics are merely the results of these cumulative lesions. Nothing is more striking than the completeness of recovery from an epileptic fit. Whatever the cause, it seems to pass away absolutely. On the supposition that the fit is due to a sudden transient cerebral anæmia, produced by cardiac inhibition, recovery follows on return of the circulation. It might be urged that if the fits are due to cardiac inhibition it should occasionally happen that the heart should stop permanently and that death in a fit should be at any rate not uncommon. If the stimulus responsible for inhibition be sufficiently intense death doubtless would result, as in the case of sudden death recorded above on exploratory puncture of the lung. But though experimental stimulation of the vagus nerve with very powerful stimulus does rarely produce permanent arrest of the heart, it is a fundamental physiological fact that there is a practically irresistible tendency for the heart to recommence beating, even during the stimulation—the so-called *vagus escape of the heart.* This escape of the heart is submitted as a feasible explanation of the recovery from the fits in those cases which are associated with actual cardiac inhibition, whilst in those dependent upon cerebral arterial spasm the fit would subside with the disappearance of the spasm.

5. *Post-epileptic phenomena.*—Though recovery may be [illegible]ry rapid after a mild fit there is commonly observed [illegible]ter the cessation of the convulsive movements a period [illegible]uring which the patient is comatose, a period frequently followed by natural sleep varying in duration. On the hypothesis of a sudden failure of the cerebral circulation there has been a profound though temporary disturbance of the nutrition of the whole nervous system. As the result there has been an intense motor disturbance. The sensory side of the brain has doubtless been the site of an equally severe disturbance, the earliest sign of which is sudden unconsciousness; but inasmuch as consciousness is requisite for the recognition of sensory disturbances the presence of such is of necessity masked. Yet the sensory apparatus would presumably be affected equally profoundly with the motor, so that marked exhaustion of the sensory elements, with resulting coma and sleep, is only to be expected. The headache following a fit is probably attributable to the intense venous engorgement of the cerebral membranes attending the convulsions. The post epileptic mental disturbances after major attacks are of interest; the engorgement of the cortex and the asphyxial state of the blood might reasonably account for them. Those occurring after minor attacks, however, belong to a different category. On the hypothesis under discussion they must be due to some transient disturbance of function in the grey matter, the result of the circulatory failure; a disturbance moreover manifesting itself after the attack and lasting for a variable time. The exact pathology of such conditions is, in the present state of our knowledge, impossible of determination, whatever view be taken of the pathology of epilepsy.

ON VASO-MOTOR SPASM IN THE BRAIN AS A CAUSE OF EPILEPSY.

This theory of the method of production of cerebral anæmia as the cause of epilepsy has had many adherents. If, as this paper is written to maintain, epilepsy is due to a sudden failure of the cerebral circulation, then vaso-motor spasm of the cerebral arteries, if intense enough, could certainly act as an adequate excitant of a fit. Direct demonstration of this as the excitant would obviously be very difficult, but if it can be proved that such vaso-motor activity does occur the possibility of its being concerned in the genesis of fits would be established. Until recently it was held that there was no evidence of vaso-motor activity in the cerebral vessels, but the demonstration of a copious networ of nerve fibres to the cerebral blood-vessels demands a revisio of the position. Harvey Cushing[6] notes that, "contrary t the positive statements of many, substances like epinephri will blanch the pial vessels over the area of its applicatio as will occasionally a jet of cold water against the brain o the faradic current used for cortical stimulation." Brod and Ferrier[7] also found that *on injecting adrenalin into th* basilar artery of the carefully removed brain, and measure ment of the outflow from the torn sinuses, with a moderat amount of adrenalin distinct diminution of the outflo occurred, and with a larger quantity complete stoppage.

The phenomena of Raynaud's disease are also worthy o study in this connexion. The pathology of this affection i far from clear. In some cases there appears to be no doub but that the symptoms are due to arterial disease; but it generally admitted that vaso-constriction in the affected par is the dominant factor. It is occasionally associated wit erythromelalgia. Certain ocular and cerebral complication occasionally occur in the course of the attacks of Raynaud' disease which are readily explicable on the supposition o an active constriction of the cerebral arteries. Thus i Raynaud's "New Researches"[8] a man, aged 59 years, wit attacks of local asphyxia also suffered from paroxysma attacks of impairment of vision. Ophthalmoscopically th arteries were found to be narrowed with here and the partial diminutions which were actually seen to occu persist for a certain time and then disappear under th observer's eyes. In another case of Raynaud's[9] a ma aged 22 years, was subject to attacks of local asphyxi which occurred when the patient went into the ope air. The patient also experienced *at the moment the commencement of the cyanosis a notable obscuration sight* which disappeared at the time when the face and hand returned to their normal colour. Ophthalmoscopically th retinal arteries were clearly seen to be narrowed when th local asphyxia was at its height and these vessels *becam widened at the moment when reaction set in.* Raynau attributed these ocular phenomena to spasmodic contractio of the retinal arteries. Other cases of narrowing of retina arteries with dimness of vision are on record. A mos interesting case published by Thomas and Osler[10] shows th concurrence of epileptic convulsions with attacks o Raynaud's disease. It seems reasonable to assume tha the convulsions were the result of vaso-constrictio affecting the cerebral vessels, and it is very interesting to note that Raynaud's disease is apt to b associated with epileptic fits. In another case o Raynaud's disease recorded by Osler[11] recurrent attacks o hemiplegia and aphasia occurred, concurrently with local symptoms in the fingers and hands. The identity of the pathological process underlying the cerebral attacks and the local syncope and gangrene can hardly be called in question. The patient died comatose with an attack of gangrene of the hand. The terminal coma is interesting; the possibility of its being due to cerebral œdema must be considered. The hemiplegic attacks might be due to arterial spasm or œdema, for, as already mentioned, these two phenomena seem to be almost interchangeable in Raynaud's disease.

Migraine.—The association of epilepsy with migraine is of considerable interest. It occasionally happens that periodical attacks of migraine are replaced by ordinary epilepsy, the migraine then ceasing. In migraine there is undoubted evidence of abnormal vaso-motor action. Chilliness of the skin is common; the temporal artery on the affected side is often contracted and hard. Relief of the pain often attends compression of the carotid artery. This, and the fact that the pain in the head is of a throbbing character, suggests that the old explanation of a vaso-dilatation of the cerebral vessels is correct. Such a dilatation of the vessels, with resultant increased tension of the dura, &c., would be enough to account for the pain. The dilatation can, moreover, be seen. Thus, Mollendorff[12] points out that "during the attacks the background of the eye on the suffering side was of a bright scarlet red, the optic papilla red and œdematous, the arteria and vena centralis retinæ enlarged, the latter knotty and very tortuous." There is much to be said for the view that the symptoms of migraine depend upon abnormal vaso-motor activity and that the headache is the result of vaso-dilatation. Gowers[13] records the following unique cases:—

[11] The Cerebral Complications of Raynaud's Disease, American Journal of the Medical Sciences, 1896, vol. cxii., p. 522.

The first case was that of a girl, aged 16 years, who had been subject to periodical attacks of migraine since the age of five years. At 13½ she had an epileptic fit during sleep, and since then three others, two during sleep and one when awake. Since the first fit the headaches had been frequent, but were preceded by a brief but very definite visual aura. The interesting point is that the single epileptic fit which occurred when she was awake was preceded by precisely the [illegible] is that local [illegible] attack

The second case was that of a man aged 60 years, who had become [illegible] aura was succeeded by severe [illegible] by quite sudden loss of con- [illegible] erved, on several occasions his [illegible] passed unconsciously. Before [illegible]

Migraine is also occasionally accompanied by transient aphasia. Conditions such as these suggest very strongly that abnormal vaso-motor phenomena are concerned, and transient spasm of cerebral arteries is not an unreasonable hypothesis. The evidence for the existence of vaso-motor activity in the brain is therefore partly direct and partly indirect. It is obviously a matter of great difficulty in clinical work to demonstrate such alterations, owing firstly to their evanescence and secondly to the fact that when they have subsided no evidence of their existence is left behind.

PETIT MAL.

A consideration of the cerebral phenomena attending cases of heart-block shows us that the attacks present an increasing degree of severity proportional to the length of the period of asystole. There may be merely a transient giddiness, a dazed feeling, a "turn," or the head may drop forward momentarily, the patient recovering himself immediately; or unconsciousness may be rather deeper though *still transient; or a fall with slight spasm*; or, finally, a severe general convulsion. Every one of these phases could be duplicated among the numerous manifestations of minor and major epilepsy. And when we compare the gradually increasing severity of the manifestations, according to the length of the period of cardiac asys[illegible] of epilepsy, the resemblance is mo[illegible] cussing the types and degrees of [illegible] remarks that "the primary types of epileptic attacks denote consecutive stages of the same series of phenomena—stages which may be arrested at any period." Among various examples given by Turner is the following: "A common form of incomplete attack is seen in fits, the aura of which is a feeling of giddiness followed by a sudden fall from loss of consciousness, but without convulsion. In these cases there are commonly found attacks of giddiness (aura), as well as complete seizures, in which the fall is followed by the usual convulsive phenomena of a major fit." In other words, the stages of severity observed are, firstly, an attack of giddiness only; secondly, an attack of giddiness followed by a fall from loss of consciousness; and, finally, the complete fit, terminating in convulsions.

A case of my own, a girl, aged 12 years, was subject to both major and minor attacks, the latter being described as attacks of giddiness. On one occasion I was feeling her pulse, she was not nervous at the [illegible] perhaps from 15 to 20, and then rapidly increased in force so that within about half a minute from its reappearance it had regained its previous state. A few minutes later its rate was 124, a rate very common in this particular case. The above attack was a typical example of many of her minor seizures.

Here was a case of cardiac inhibition in what would be called *petit mal*. The cessation of pulse and the child's cry were, I think, simultaneous. Had the cardiac arrest been of longer duration a fully developed major attack would doubtless have occurred. Again, in Finny's case of bradycardia recorded in the first lecture the attacks varied from what were called "weak turns" to "slight fits" and "severe fits." The case was at first regarded as one of *petit mal*. *It is very interesting to note* that the slight fits came on with soreness or sharp feeling in the stomach and left side of the thorax, which would then extend up to the right side of the chest into the head and eyes—a definite aura, in fact. Pallor of the face occurred, the eyes would turn up to the right side, and the hands would fidget and the fingers clutch at the sheets. The patient always came out of the fit in a frightened and slightly dazed manner, and the eyes had a strained and somewhat blind look for some minutes. Here we have an aura, and if it had occurred in a case of idiopathic epilepsy it would have been regarded as typical, but it occurred in a patient whose attacks were unquestionably secondary to cerebral anæmia from heart block. Whether the aura was due to sensations derived from the peripheral vessels and heart or to cerebral changes resulting from the cessation of the circulation it is difficult to say, but there can be no doubt that it was of circulatory origin. Finally, in the severe fit in the same patient the onset was more sudden, there were convulsive movements of limbs, and the patient came out of it very confused and was dull and nervous the whole day following. Such resemblances are too close to be due to mere coincidence. It is difficult to conceive of any other explanation than an identity of cause. The cause was unquestionably sudden failure of the cerebral circulation in the case described and the conclusion seems inevitable that the fit of idiopathic epilepsy is determined in a similar way. But it cannot be claimed that cardiac inhibition occurs in all cases of minor epilepsy. Moxon quotes Hughlings Jackson's observations of the disappearance of the pulse at the onset of attacks of *petit mal*. I myself was on two occasions feeling the pulse of a boy subject to minor attacks when one supervened. No arrest occurred, nor was there any obvious change in the pulse-rate. A transient spasm of the cerebral arteries may underlie these attacks. The boy was unaware of his attacks, whereas the girl recognised them and dreaded them very much, but they are clearly cases of very different type.

INFANTILE CONVULSIONS.

The similarity between infantile convulsions and those of idiopathic epilepsy is so close that the probability of the same factor underlying the two conditions must be very considerable. The vaso-motor system of the child is much more unstable than that of the adult and the ease with which emotional disturbance and shock are produced is notorious. In a considerable number of cases the occurrence of apparently ordinary infantile convulsions is the starting point of chronic epilepsy. It seems hardly open to doubt but that the large numbers of alleged causes of infantile convulsions, such as teething, rickets, worms, acute infections, gastro-intestinal disturbance, fright, and so on, must exert their influence *viâ* some common factor. Such a factor might be, as suggested, abnormal vaso-motor and cardio-motor systems with a ready liability to attacks of acute circulatory failure, either from cardiac inhibition or from splanchnic dilatation. If this factor is brought into play once only, we have an isolated convulsion; if only a few times, we have a few convulsions. If, however, it is brought into action over and over again chronic epilepsy is the result.

The convulsions met with at the onset of acute infections in childhood are worthy of mention. Under similar conditions rigors are common in the adult, so much so that it is almost an aphorism that under such conditions a convulsion in a child is the equivalent of a rigor in an adult. I have, however, once seen a convulsion at the onset of pneumonia in a non-epileptic adult. A rigor is associated with marked cutaneous vaso-constriction with pallor and sensation of great cold. The sensitive cardiac and vaso-motor systems of the child may not be able to adjust themselves to a severe vascular crisis, and it is to be noted that the old-established

---

[illegible], p 307.

method of cutting short convulsions in infancy by means of immersion in a warm bath by producing vaso-dilatation of the skin lowers the blood pressure.

JACKSONIAN CONVULSIONS.

Local stimulation of the cerebral cortex by the electric current, or by the presence of a cortical tumour, are both competent to produce that type of convulsive seizure commonly known as Jacksonian. The muscles first involved in the convulsive movements are those related to the area stimulated, but the spasms rapidly spread to other groups, and finally the whole musculature of the body may be involved. Several possible explanations of this march of events must be considered.

1. It might be due to a spread of the current, but if so one would expect that the spread should occur at the moment of application of the current, and, moreover, the fact that areas very remote from the one primarily stimulated are involved—for instance, the opposite side of the brain—renders such an explanation very improbable.

2. To a spread of the excitation, the view commonly held. That the area of musculature involved in the convulsive movements gradually widens is proof that the excitation spreads, but it affords no explanation as to *how* it spreads.

3. It might be due to a spreading vaso-constriction of the cerebral blood-vessels, the resulting anæmia bringing about the spread of the convulsions. I have referred above to evidence suggesting that the cerebral vaso-motor mechanism is a much more active one than is generally assumed, and I would draw attention again to Harvey Cushing's observation that faradic stimulation of the cortex can produce a paling of the grey matter.

The phenomena of Jacksonian fits dependent on tumour might be susceptible of the same explanation—viz., a spreading vaso-constriction; but it is certainly difficult to correlate this group of fits and those due to absinthe with cerebral anæmia, and the possibility that they depend on a different mechanism must be admitted.

THE SYMPTOMS FOLLOWING UPON SUDDEN AND PROLONGED CEREBRAL ANÆMIA.

So far we have considered the results following sudden and very transient cerebral anæmia. The symptoms resulting from a more prolonged arrest of the cerebral circulation are not less interesting. In the paper already referred to on death occurring during or after exploratory puncture of lung, in addition to one case of sudden death I recorded two cases in which death occurred three and five days respectively after the puncture of chest. I will briefly note the salient features of one of these two cases:—

Old pulmonary tuberculosis; chronic left basal pneumonia; exploratory puncture; syncope, convulsions, left hemiplegia; death three days later.—The patient was a male, aged 52 years, under the care of Dr. T. D. Acland at Brompton Hospital; he was admitted on June 14th and died on June 17th, 1890. On examination the physical signs were suggestive of a localised collection of fluid at the left base. A puncture was therefore made just under the angle of the scapula between the eighth and ninth ribs. The patient almost immediately passed a large quantity of urine, turned pale, and fell backwards. Respiration ceased entirely at once; the heart beat most irregularly and radial pulse was not to be felt. Ether was inje the interrupted current was applied, and ar maintained for half an hour. He then had a fit in which the left arm became firmly flexed at the elbow, the thumb flexed into the palm, the fingers over the thumb, and the hand flexed at the wrist. The left leg was not affected. The eyes were deviated to the right and the pupils widely dilated. When examined a few hours later he was still unconscious; the eyes moved only to the right, and the pupils reacted very sluggishly, if at all, to light. The conjunctival reflex was present; the fundi were normal. The left arm at times moved slightly and then would become rigid and flexed; the left leg was rigid, the knee-jerk was exaggerated, and ankle-clonus was obtained with difficulty. There was also slight left-sided anæsthesia. On the morning of June 15th there was obvious left hemiplegia, with much twitching of the muscles of the left side of the thorax and abdomen. In the evening the right arm was rigid and fixed, the right leg was extended and constantly twitching; ankle-clonus was obtained on both sides—more briskly on the right. On the morning of the 16th he was still unconscious; the left hemiplegia and anæsthesia still persisted; the right arm was rigid with clonic spasms; ankle-clonus was absent and the knee-jerk could not be elicited on either side. Several convulsive seizures occurred during the evening; the arms were rigidly flexed across the chest, with twitching movements in both; there was much grinding of the teeth and clenching of the jaws; the head and eyes were moved from side to side. The left leg was somewhat rigid and there was much twitching of the foot; both knee-jerk and ankle clonus were obtained. The right leg was very *rigid with twitching of the foot; the knee-jerk was brisk.* The left optic disc was apparently swollen and blurred, with one flame-coloured patch; the right cornea was hazy, and the disc looked blurred. The temperature rose to 101° F. before death, at 11 A.M. on June 17th.

Post-mortem examination.—The left lower lobe was in a condition of chronic pneumonia with localised pleural adhesion. The upper lobe and the right lung showed fibroid and calcareous changes.

Brain.—The pia mater generally was slightly opaque. The dura al was slightly thickened, but there were no morbid adhesions. Th vessels at the base of the brain were healthy. The brain tissue w fairly firm, and no obvious lesion could be detected in any part.

In a case recorded by Hubert Armstrong[15] the initi symptoms, though almost equally severe, were recovere from. Several fatal cases presenting similar features are o record in which the symptoms followed pleural lavage. Th causation of the cardiac arrest in these cases is of grea interest. In some experiments[16] performed in conjunctio with Professor Brodie at the laboratories of the Roy Colleges of Physicians and Surgeons, with the object c ascertaining which of the afferent fibres of the vag cause inhibition of the heart when their central ends ar excited, we found that the pulmonary fibres were by f the most effective in this respect. If the root of the lun be exposed in an animal and any of the pulmonary branche stimulated a typical arrest of the ventricular contraction, a shown by the blood pressure record, is produced. At th same time marked arrest of respiration occurs from excita tion of the respiratory centre. The vaso-motor centre is al inhibited and produces a further fall in blood pressure, apa from that due to the cardiac inhibition, as proved by the fa in blood pressure produced in an animal whose cardio-inhib tory fibres have been paralysed by atropine. The subject ha also been studied by Capps and Lewis[17] who concluded fro experiments on animals with artificially induced pleurisy an from observations on the blood pressure of man durin aspiration of pleural effusions that the pleural fibres of th vagus can give rise to a very active lowering of bloo pressure, and that this may be brought about either from reflex vaso-motor effect or a reflex cardiac inhibition.

SIMILAR SYMPTOMS RESULTING FROM PROLONGED CHLOROFORM SYNCOPE.

The conclusion that the cerebral manifestations in th above cases are due to prolonged cerebral anæmia supported by the facts published by T. A. Green in his pap on Heart Massage as a Means of Restoration in Cases c Apparent Sudden Death.[18] Numerous cases of recovery aft chloroform syncope as the result of massage of the heart a on record, but in some, although the heart has been induced t beat apparently normally, death has resulted after a varyin period with a train of symptoms practically indistinguishab from those noted in the above cases. The fact that in thes cases of chloroform syncope the heart had ceased to beat fo varying periods and that therefore the cerebral circulatio was for a time at a complete standstill leaves no room fo doubt but that the cerebral symptoms are to be attributed t the cessation of the blood flow through the cerebral arteries Green's first case is as follows:—

A boy, aged nine years, was being operated on for congenit umbilical fistula. During the early stage of the operation respiratio stopped, "the lips became cyanosed, the skin pale, and the pupils of th eyes widely dilated and insensitive. No pulse could be felt at th wrist and on auscultation no heart sounds could be heard. The respira tion continued s minutes later." 25 minutes after under the left costal arch and commenced cardiac massage through th diaphragm. The apex of the heart was felt to be quite immobile and flaccid. Rhythmical compression of the heart was practised at a rate of about 70 per minute. After about two minutes a slight fluttering of the heart was observed and at the same time the pupils contracted slightly. Within a few seconds it began to beat with more than normal vigour at a rate of about 90 or 100 per minute. Artificial respiration had been continued the restoration of the pulse nsciousness never returned; trunk developed; he broke out into severe perspirations and the pulse and respirations increased in frequency. The muscular spasms were severe enough to necessitate the administration of morphine and chloroform. Death occurred 24 hours after the heart beat and respiration had been re-established.

Green also records a second but less striking case occurring under his own observation, but death occurred one and a half hours after the heart massage had been commenced. Green reviews the literature and gives a synopsis of 40 cases of heart massage for chloroform syncope, in several of which death occurred some hours after the heart failure with symptoms similar to those observed in his cases.

ON THE ETIOLOGY OF ACNE VULGARIS AND ITS TREATMENT BY VACCINES.

By ALEXANDER FLEMING, M.B., B.S. LOND.

(From the Laboratory of the Inoculation Department of St. Mary's Hospital, Paddington, W.)

AN accurate conception of the etiological factors in the various bacterial diseases has of late years become increasingly important in view of the specific treatment of such diseases by means of vaccines. I here propose to set forth some investigations I have carried out on the bacteriology of acne vulgaris, which seem to show that this condition is not simply one of staphylococcic infection, but is largely due to a specific bacillary infection.

In 1893 Unna[1] first described a bacillus which he found in the lesions of acne vulgaris and to which he gave the name "acne, bacillus." He did not isolate the bacillus in culture but found it constantly in sections and smears of comedones and pustules, and he concluded on histological grounds that the bacillus described by him was the probable cause not only of the comedo but also of the pustule. His three chief reasons for this belief were (1) that the bacillus was the only organism constantly present; (2) that in the comedo the bacilli were situated especially in the deeper part, whereas the other organisms present—e.g., staphylococci or bottle bacilli—were found near the surface; and (3) that the histological characters of the pustules were not such as were associated with other staphlylococcic infections.

Sabouraud,[2] in 1897, described the bacillus as occurring in sebaceous plugs which can be squeezed out of seborrhœic skins. He claimed that it was the cause of oily seborrhœa and also of alopecia areata, which he considered a localised seborrhœic condition. He was the first to describe accurately the cultural properties of the microbe, which he named the "bacille de séborrhée grasse." He considered that the indurated nodules and the pustulation of acne were due to a superimposed secondary infection with staphylococci.

Gilchrist,[3] in 1899 and later in 1903, states that a bacillus which is apparently identical with that described by Unna and Sabouraud is the cause of all the lesions of acne. He recounts that he found the bacillus in all the smears of acne pustules, and in about 30 per cent. of cases he obtained pure cultures from these pustular lesions. He rechristened the organism the "bacillus acnes."

Whitfield,[4] in his book on skin diseases, concludes as the result of his investigations that the acne bacillus is the cause of the comedo, but that the pustule is the result of a secondary staphylococcic infection.

The acne bacillus, as seen in smears of comedones and pustules, is a small Gram-staining bacillus varying in length from under 1μ to 3μ or 4μ and about ½μ wide. The younger forms stain evenly and darkly, but commonly the older forms show one or more deeply stained dots in their interior. These dots may be situated at the poles or they may be present along the whole length, resembling a chain of small cocci. The tenacity with which these bacilli retain Gram's stain is not nearly so marked as in the cas[illegible] quite easy to so stain a film [illegible] while the cocci are deeply [illegible] of the bacilli in pus is very irregular, single bacilli are present, pairs are common, especially arranged as a V, and large irregular groups are almost invariably to be seen; the microscopical characters of the bacillus in pus films and also in smears from cultures are very similar to some of the diphtheroid bacilli one meets with in superficial ulcers and elsewhere, and it is very probable that it is to this group that the bacillus belongs. The bacilli are often found inside the pus cells, and the same film may show phagocytosis of both bacilli and cocci, indeed one may see both taken up by the same cell. In the comedo the bacilli are in general shorter and stouter, and stain evenly, while in the pustule longer forms are seen with very irregular staining.

Smears from acne pustules practically always show the presence of the specific bacillus. Often no other organism is to be found, but in many cases staphylococci are evident in greater or less numbers. Other organisms may be seen, but they are not common and cannot have much influence on the etiology of the lesion. Gilchrist found the bacilli in every one of his smears, and in only very few have I been unable to find them with the greatest ease. In six cases, however, I was unable to find any organism at all, but from two of these I was able to obtain pure cultures of the bacillus. I found only acne bacilli in 44 per cent. of the pus films I examined, acne bacilli with staphylococcus in 53 per cent., in six cases no organisms were observed, while in one case,[5] only bottle bacilli were evident. The films were stained in all cases by Gram's method, which is much the best for the demonstration of the organisms. The bacilli in most cases were very numerous and the cocci when present were usually relatively few in numbers, but in some cases (roughly about a third of those cases where both organisms were present) the cocci were very numerous and far outnumbered the bacilli.

Unfortunately the very slight power of growth of the acne bacillus on artificial media makes it very difficult to get from cultural methods a true estimate of the frequency of its occurrence. Unna, when he described the organism, had not obtained cultures, and Sabouraud cultivated it from comedones and seborrhœic lesions. Gilchrist, however, claims to have cultivated it from acne pustules in 96 cases out of 145, 44 times mixed with staphylococcus and 52 times pure. My success in obtaining pure cultures has not been so great as was Gilchrist's, for out of 132 cultures from acne pustules I could only get pure growths of the bacillus on 13 occasions. Of the other cultures 35 were sterile, 40 grew both acne bacillus and staphylococcus, and 44 grew only staphylococcus. The large number of sterile cultures is due, I believe, to the fact that the bacillus only grew with the greatest difficulty on some of the media used. In some of the cultures, although staphylococci grew yet so few colonies developed that it suggested an accidental contamination, especially as it was impracticable to efficiently sterilise the skin in some cases. The sterilisation of the skin was effected by wiping it over with pure lysol and washing this off quickly with spirit. The pustule was then pricked and the contents squeezed out and a loopful transferred to an acid agar slope and planted out *en masse*. If the pus be spread thinly over the surface of the medium no growth of the bacillus will be obtained. The same applies to subculturing the bacillus and many tubes where it is only moderately thickly planted fail to grow.

In the large deep-seated pustules two elements are to be observed in the pus. Where the contents are squeezed out, first appears an opaque semi-fluid mass, consisting chiefly of pus cells. If this is wiped away and further pressure is made a gelatinous mass is extruded consisting largely of epithelial cells and representing probably a broken-down comedo. In making my cultures I have preferred to use the purulent material for two reasons: firstly, because in investigating the causation of the pustules it seemed hardly fair to use for cultural purposes what I considered to be a degenerated comedo, and secondly, in those cases where I examined films of both constituents of the pustule I found that where staphylococci were present in the pus they were present also in the gelatinous substance. A large number of my cultures were taken also from the small superficial pustules, and these were the more productive in pure cultures of the bacillus.

The subordinate rôle played by staphylococci in some cases of acne was well illustrated in one patient who suffered from comedones and pustules on the back and shoulders. Films of these pustules I have examined over 50 times and only on a few occasions could I find any cocci present, while of eight cultures on acid agar five yielded pure cultures of the acne bacillus, two were sterile, and staphylococcus grew in only one. Of eight cultures made on ordinary agar six were sterile and on the other two a few colonies only of staphylococcus developed.

In cases where a pure culture of the bacillus was obtained no change was observed in the culture tube for about three days but an increase in the transparency of the mass of pus. Then three or four small white spots appear, representing colonies of the bacillus, and these increase slowly in size till at the end of a fortnight they may have the diameter of 1 millimetre. The fact that only three or four colonies appeal from a large loopful of pus indicates the feeble character of the growth, as films of these cases have shown that a very large number of bacilli must have been present.

[5] A man, aged 48 years, who had had comedones and pustules on the back for only about two years.

It has been suggested that the reason of frequent failure to cultivate staphylococcus from an acne pustule is that in acne, as in some other coccal infections, the cocci are limited to the walls of the abscess, but this does not, I think, apply to acne, as sections reveal that in this condition the cocci are more or less scattered throughout the pus, so that when one takes a large quantity of pus it is hardly conceivable that they should be missed.

In culture the bacillus presents exactly the same appearance to that already described as being observed in pus films. Involution forms are not prominent and it retains its staining properties in a culture three months old. Definite branching forms occur, especially in broth cultures. It does not form spores. It grows best at 37° C. and growth ceases at room temperature. Sabouraud gives the thermal death point as 75° C., and he has taken advantage of this to separate it from other organisms. Only once have I been able to separate it from staphylococcus by heating to 60° for half an hour. On the other occasions I have tried this method I was unable to obtain any growth after heating. Other methods of separation have been recommended, such as soaking comedones in absolute alcohol when the cocci only are said to be killed or *leaving the culture for three months when the cocci are said* to have died out, but with these I have had no success. The cultural characteristics are as follows:—

Broth.—This becomes cloudy in two days, and on the sides and bottom of the tube a heavy flocculent deposit is produced. When growth ceases in about a fortnight the fluid is quite clear with a heavy deposit at the bottom. The broth is not rendered acid by the growth.

Acid agar (ordinary agar rendered faintly acid with HCl).—On the third day a small rounded colony appears, increasing slowly in size for a fortnight, when it may measure up to one millimetre. The colony remains white and much resembles that of staphylococcus albus.

Acid glycerine agar.—The growth is similar to that on acid agar but not quite so rapid. When old it becomes heaped up and darkens in colour till it is almost black.[6]

Sabouraud's special medium.—I have found the rate of [illegible]owth on this much slower than on either of the two pre[illegible]ing solid media, but the type of growth is the same. [illegible]ordinary agar no growth occurs.[7] No growth was [illegible]ined in broth containing 1 per cent. of the various [illegible]gars.

Oleic acid glycerin agar.—This medium was suggested to me by the constant association of the bacillus with the fatty secretion of the sebaceous glands. Agar is neutralised with hydrochloric acid, 2 per cent. glycerine and 0·1 per cent. oleic acid is added, and the medium is then tubed off and sterilised in the autoclave in the usual way. Subcultures on this medium showed an appreciable growth in 24 hours, and in two days the surface was covered with a mass of white opaque colonies resembling very much those of staphylococcus albus both in size and appearance. This is by far the most suitable medium I have tried for the bacillus.

We have now to examine the serum reactions of infected persons to the acne bacillus. Gilchrist found that the serum of his patients agglutinated the bacillus in a hundred-fold dilution while his controls of healthy serum only agglutinated in a fifty-fold dilution. These results I have been unable to reproduce in their entirety. The sera were tested with five strains of the bacillus and three of the sera were derived from the same individuals from whom three strains of bacillus had been isolated. Of these three one showed no agglutinating power, one agglutinated the homologous strain in an 18-fold dilution, and the other agglutinated its own bacillus in a 54-fold dilution, and at the same time showed agglutination with one of the other strains to a less degree (six-fold dilution). Two patients who were being inoculated with a certain strain of bacillus and improving rapidly agglutinated this strain in a 32-fold dilution. The normal sera showed *no agglutinating* power in a *four-fold dilution.*

As regards the opsonic power I have tested 26 patients and have found that the opsonic index varies considerably, much more than does that of serum from healthy people. The indices obtained varied about the normal in the following manner:—

From 0·60 to 0 80 = 5
,, 0·81 ,, 1·00 = 6
,, 1·01 ,, 1·20 = 4
From 1·21 to 1·40 = 5
,, 1·40 ,, 1·60 = 6

Thus it will be seen that there is a tendency to an increase in the production of opsonin in infected persons—a condition frequently met with in other infections—e.g., gonococcus, bacillus coli, &c.

The *opsonic indices of seven apparently healthy people* were done in all 42 times, and these may be tabulated as follows:—

Under 0·80 = 1
0·81 to 0·90 = 6
0 91 ,, 1·00 = 13
1·01 to 1·10 = 15
1·11 ,, 1·20 = 6
Over 1·20 = 1

As regards the *pathogenicity of* the bacillus to the lower animals Gilchrist found that it killed mice and guinea-pigs in one or two weeks and from the pus at the seat of inoculation and from the heart's blood he obtained pure cultures of the bacillus. My observations in this connexion are limited to the inoculation of week-old broth cultures of two strains of bacillus into two-guinea pigs, neither of which suffered any *inconvenience.*

The next question to be examined was the possibility or otherwise of reproducing the disease by inoculation of the bacillus directly into the skin of a susceptible individual. Last November I rubbed *vigorously into the skin* of the forearm of a person suffering from acne a week-old broth culture of an acne bacillus freshly isolated from him. At the same time the same culture was vigorously rubbed into the arm of one of my colleagues who has never suffered from acne. In the latter case only a negative result was obtained but in the case of the susceptible individual after two days several of the hair follicles of the area rubbed over became inflamed and in five days definite pustules formed which persisted a week, then began to dry up, *although the lesions* did not disappear for over a month. On the fifth day and again on the twelfth day films of these pustules were examined and no organisms other than the acne bacillus could be discovered. This, then, would seem to show that this bacillus is capable of producing a pustular folliculitis in a susceptible person.

Of the other organisms present in acne I need only mention two—viz., the *staphylococcus and the bottle bacillus. The* former is present in many comedones as well as in pustules and sometimes in considerable numbers; indeed, Sabouraud in his earlier researches had great difficulty in obtaining culture from these comedones of the acne bacillus free from staphylococci. Staphylococcus aureus seems to be uncommon in these lesions. I have only grown it on two occasions, once from a large pustule—almost a furuncle—following an excessive dose of staphylococcus vaccine, and again in what seemed an ordinary slight case of pustular acne. All my other staphylococcic cultures were of the white variety and only very few of those tested liquefied gelatin. Of the others there were two main types—one very opaque and white, while the other was greyish semi-transparent, having a very flat colony with irregular margin which spreads to a considerable size over the agar.

The bottle bacillus is a large organism shaped something like a bottle and presenting an appearance very like a yeast. I have not succeeded in obtaining cultures. It occurs in the more superficial part of the comedo and is to be found constantly also *in dry seborrhœic conditions of the scalp* or elsewhere where its presence may be of great diagnostic value.

Before going on to the question of the treatment of acne I would like to direct attention to the evidence that the acne bacillus may be and frequently is the cause of pustulation. As stated above, Unna and Gilchrist thought that the pustulation was of bacillary origin, while Sabouraud, and more recently Whitfield, believed it to be a secondary coccal infection. The last observer gives as his reasons for holding to the coccal origin of the pustules (1) *that staphylococci* can always be cultivated from the pus; (2) that films of pus often show cocci ingested by leucocytes, thus proving that they are not merely a surface contamination; and (3) that patients with pustular acne have a low opsonic index to staphylococcus. As regards the first reason the cultural evidence detailed in an earlier part of the paper would seem *to indicate that there is a fairly large percentage of cases* where one obtains either no growth at all from the pustules or a growth of the acne bacillus. This bacillus one can practically always see in films of pus and it is probably only because of its very feeble powers of reproduction on artificial media that one does not obtain a culture every time. With regard to the ingestion of the cocci by leucocytes if this be a proof that they are exerting a pathogenic action, then much more does this apply to the acne bacillus, for in pus films one finds bacilli inside the pus cells with much greater frequency than one does cocci. Sometimes, as I indicated above, one finds both phagocyted in the same film or even both inside the same pus corpuscle. The third reason adduced—that of the low opsonic index—applies, I think, only to those individuals in whom there is a staphylococcic as well as a bacillary infection. I have shown, however, that these patients also exhibit abnormal opsonic indices to the acne bacillus.

---

[6] This darkening on glycerine media may be due to the formation of the same substances which cause the blackening of the free end of the comedo

[7] Since writing the above I have su[illegible] from the contents of a superficial culture plante[illegible] 14 days' incubation four small colonies of [illegible]earances similar in all respects to the acne bacillus.

Having now treated in a more or less complete manner of these objections I would adduce the following contentions in favour of the pyogenic nature of the bacillus. 1. It is constantly present in the pus as shown by examination of films. 2. It is frequently the only organism present in pus. 3. It can frequently be recovered from the pus in pure culture. 4. Inoculated into the skin of a susceptible individual it produced a pustular folliculitis and examination of the pus showed no other organism to be present. 5. Inoculated into animals it produces an abscess at the seat of inoculation from which the bacillus has been recovered in pure culture. (Gilchrist.) 6. The serum of patients affected with acne agglutinates the bacillus in some cases. 7. The opsonic indices of patients to the acne bacillus vary considerably from normal. 8 Large doses of a vaccine derived from the acne bacillus have, as we shall see later in connexion with the treatment, induced a marked negative phase characterised by the appearance of fresh pustules from which the bacillus has been recovered in pure culture. 9. A vaccine of this organism has a marked beneficial effect on the condition. 10. When a patient has a high opsonic index to the bacillus his condition improves, but when the opsonic index is low fresh pustules appear.

We now come to the question of the treatment of acne vulgaris by means of bacterial vaccines. I think we may take it is definitely proved now that in a localised infection, when one inoculates the patient with appropriate doses of a carefully prepared vaccine derived from the infecting organism, one obtains a definite beneficial effect. This has been shown by very many observers since Sir Almroth Wright first directed attention to the curative properties of these vaccines, and taking this broad principle as the basis for our work we would expect, from what I have advanced as to the bacteriology of acne, that a vaccine of only one organism, whether it be staphylococcus or acne bacillus, would not be sufficient in all cases. The treatment of acne by means of staphylococcus vaccine has been repeatedly discussed by Sir Almroth Wright[3] and others, and I here propose to deal mainly with the treatment by means of a vaccine of the acne bacillus alone or in combination with staphylococcus.

Very frequently in treating a case of acne with staphylococcus vaccine it is found that there is a definite improvement for a time then the condition remains stationary in spite of any modification in the dose or character of the staphylococcic vaccine. This is exactly what would be expected from a consideration of the bacteriology, as it is only in a certain number of cases that the staphylococcus is present, and even when present it is not responsible for the *whole condition. We can*, therefore, *divide* cases of acne vulgaris for therapeutical purposes into three classes. The first will consist of those cases in which the comedo is the dominant feature, with, also, some of those which have progressed further to the indurated and pustular stages. In this class of case the acne bacillus is the offending agent and the staphylococcus if present at all is playing a subordinate rôle. This class, therefore, may be treated with a vaccine of acne bacillus alone. The second class consists of a large number of the indurated and pustular varieties where both staphylococcus and the acne bacillus appear to be playing an active part in the causation of the inflammatory process. The therapeutic requirements of this class are best met with a mixed vaccine of staphylococcus and acne bacillus. The third class consist of those less common cases where there is a more acute inflammation, tending almost towards a furuncular form. Here microscopical examination will show that the staphylococcus is the chief offender and treatment should be directed at first against this factor, not forgetting, however, that at the basis of the condition there is an acne bacillus infection.

I would here lay stress on the importance of the microscopical examination of smears of the pustules before vaccine treatment is embarked on in order that some certainty may be arrived at as to which class the patient belongs.

The vaccine used was derived from a three weeks' old culture on acid agar and was made and standardised in the usual way. In two cases opsonic estimations were made almost daily over a period of six weeks, and the charts show that the index varied exactly as it does with inoculations of other organisms. One of these charts relating to a case of mild pustular acne is here reproduced. A dose of 10,000,000 acne bacilli caused a marked negative phase followed by a rise and a subsequent drop. Smaller doses of 6,000,000 showed no negative phase. The clinical condition showed a very marked correlation with the index—i.e., when there was a low index fresh spots appeared and when the index rose the condition improved. This very close correlation rendered the continuance of the opsonic estimations unnecessary for guidance in treatment, the clinical condition affording a good and much more easily observed guide. I may mention here that this patient, who exhibited a marked negative phase with 10,000,000 bacilli, had previously had administered a dose of 50,000,000 which was followed by a very luxuriant crop of pustules, and from these pustules pure cultures of the acne bacillus were obtained.

The stock vaccine in use in this laboratory was derived *from a pustule* on the face of a woman, aged about 25 years, who had had very bad pustular acne on the face and shoulders for many years. She had been having staphylococcic inoculations at intervals of ten days for about a year.

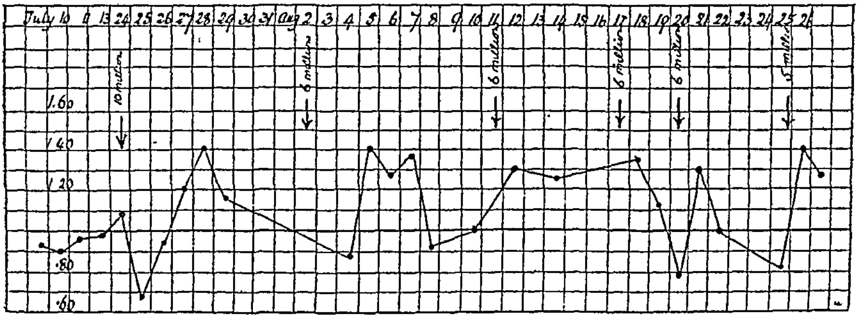

Chart showing the effect on the opsonic index to the acne bacillus produced by inoculations with a vaccine of that organism.

---

[3] THE LANCET, March 29th, 1902, p. 874; Brit. Med. Jour., 1904.

The condition had improved somewhat at first but for several months had been almost stationary. She then had the same stock staphylococcus vaccine, combined with 20,000,000 of her own acne bacillus vaccine. This was followed by the appearance of fresh pustules and the aggravation of existing ones. Ten days afterwards another inoculation was given of staphylococcus, with this time only 10,000,000 acne bacillus, and inoculations were given regularly of the same doses of the same staphylococcic vaccine as she had previously been having, combined with doses of acne bacillus varying from 5,000,000 to 10,000,000 and in three months almost all traces of acne had disappeared. Later she discontinued treatment and a slight relapse occurred, but this has again improved with the mixed staphylococcic and acne bacillus vaccine.

Another case was that of a girl, about 26 years of age, who had had very bad pustular acne on the face for several years. The face was covered with deep indolent pustules; a film of pus showed no organisms; and of cultures from four pustules two were sterile and two showed a scanty growth of staphylococcus. From July till the end of September last year she had doses of mixed stock staphylococcus and acne bacillus vaccines in doses of 100,000,000 to 250,000,000 of the former and from 5,000,000 to 20,000,000 of the latter, with hardly any improvement. It is worthy of note that while a dose of 250,000,000 staphylococci + 10,000,000 acne bacilli produced hardly any negative phase, the next dose of 250,000,000 staphylococci + 20,000,000 bacilli was followed by a marked exacerbation of the pustulation, indicating the importance of the bacillus in the causation of these lesions. From the end of September till the beginning of January she had the same doses of staphylococcus with doses of from 5,000,000 to 10,000,000 of an acne bacillus obtained in pure culture from her own pustules, and from the very first her condition improved till on Jan. 7th of this year all suppuration had disappeared from the face with the exception of one very small superficial pustule.

Another case was that of a girl, aged 20 years, who had had very bad facial acne for five years. Films of pus showed many acne bacilli and in some pustules staphylococci were also to be seen. From Sept. 3rd, 1908, to Dec. 3rd she was treated with stock vaccines of staphylococcus (200,000,000) and acne bacillus (5,000,000 to 8,000,000) without showing any definite improvement. From Dec. 3rd to Jan. 22nd, 1909, she has been having the same doses of the same staphylococcus with 8,000,000 of an acne bacillus derived from her own lesions. The improvement was immediate and marked, and now there is practically no pustulation, merely some indurated nodules and many scars.

These cases illustrate the fact that not all the cases will show improvement when treated with a stock vaccine, and this is exactly in accordance with what one finds with other organisms, such as streptococcus or bacillus coli. They also furnish very strong evidence that the bacillus is largely responsible for the suppuration. The first case had been treated with staphylococcus for months, and it was only after acne bacillus vaccine was administered that a rapid improvement in the pustulation was observed. The first and second of these cases show that when an excessive dose is given them a definite negative phase is induced, although the dose of staphylococcus is unaltered. The second and third cases show that although the stock vaccine of staphylococcus combined with the stock vaccines of acne bacillus was of little avail, yet the same doses of the same stock vaccine of staphylococcus with an autogenous acne bacillus vaccine rapidly got rid of the suppuration.

While these cases illustrate the fact that in some cases an autogenous vaccine of acne bacillus is necessary, yet experience has shown that in the vast majority of cases great improvement has been induced by the inoculation of a stock vaccine combined with staphylococcus if an examination of films has revealed that that organism is present. The dose used has varied from 4,000,000 to 10,000,000 and the interval between inoculations from one to two weeks. The guide to treatment has been the appearance of fresh lesions either during the period of low resistance following the positive phase when too long an interval has been allowed to elapse or in the next two or three days after an inoculation indicating that too large a dose has been administered. By watching these signs and working the dose up till it just fails to show any "negative phase" clinically one obtains the maximum benefit from the vaccine. In this way a large number of cases of acne in all its stages have been greatly improved and in a fair proportion the lesions have totally disappeared. On cessation of treatment in several instances, especially in some cases where attendance ceased before the condition had entirely disappeared, there was a recrudescence of the disease, which, however, rapidly gave way to subsequent treatment.

It is interesting in view of Sabouraud's contention that this bacillus is the cause of seborrhœa and of alopecia areata to note the effect of treatment on a patient—a woman aged 25 years—who suffered from comedones on the face and a rapid loss of hair which had been persisting for some months in spite of ordinary treatment. In October last she was first inoculated with the acne bacillus and from the first week after this the loss of hair practically ceased. Since that time she has had inoculations every 7 or 14 days, and there has been no return of the loss of hair. One cannot argue from one case, but it is possible that if, as Sabouraud maintains, seborrhœa of the scalp is due to this bacillus and the loss of hair is due to seborrhœa, then inoculations with the bacillus may prove of benefit in checking this loss.

THE PHYSIOLOGICAL AND THERAPEUTICAL PROPERTIES OF THE SERUM OF MILK (LACTO-SERUM).[1]

By DR. RAOUL BLONDEL,
CHEF DE LABORATOIRE AT THE MATERNITY HOSPITAL, PARIS.

(*Specially Translated for* THE LANCET.)

WHEN the casein of milk is separated by coagulation the residue is a serous liquid commonly called whey. If the coagulation has been produced by means of an acid the whey contains a certain amount of albuminoid substances, but if rennet (*le ferment lab*), assisted in its action by a salt of calcium, has been used, only traces of such substances remain. The present investigation was commenced in the year 1902 and the first results were made known in a preliminary note read at the Medical Congress held in Madrid in 1903. In conducting it I took no account of the dietetic uses of whey—a subject on which many works have been published, and I administered the lacto-serum by the hypodermic method which had not been previously employed so far as I am aware.

My first observations were made in Dr. Maygrier's obstetric wards at the Charité, where I held an appointment, and in them lacto-serum sterilised in an autoclave was used. Sterilisation by heat, however, has the disadvantages that the product changes in colour if it contains a trace of alkali and becomes turbid if it contains a trace of acid, absolute neutrality being almost impossible of attainment in a solution of amphoteric reaction. For these reasons recourse was ultimately had to sterilisation without heat by filtration through a d'Arsonval bougie. The d'Arsonval bougie is a porcelain tube like the Chamberland bougie, but larger and thicker, in which the organic liquids to be filtered are forced through under pressure of carbonic acid gas. The pressure is considerable and causes a filtration of thick albuminoid liquids which will not traverse ordinary filters. The lacto-serum, whenever it is well prepared and a little patience is used, can be filtered through ordinary bougie filters. The lacto-serum used by me is derived from cow's milk; it is a clear fluid, almost tasteless, and practically isotonic; it contains the mineral salts of the milk, occasional traces of albumin varying with the method of preparation, and more especially the natural ferments of the milk which are destroyed by sterilisation with heat but remain in solution after filtration without heat as above described. This fluid possesses some very interesting properties. As regards its saline constituents it behaves like a solution in which chloride of sodium, milk sugar, and phosphates of the alkalies and alkaline earths predominate. As regards its ferments, it has a resemblance to extracts of animal organs and to animal serums; like them, it contains certain oxydases, the importance of which is only beginning to be known and which impart to all serums several properties in common. This last and very remarkable fact was suspected by Pasteur and has been confirmed by the successful employment in different diseases of a serum such as that of Dr. Roux, which has produced such good effects in diphtheria that it deserves to be called a specific.

---

[1] Memoir communicated to the Paris Academy of Medicine on April 9th, 1909.

The ferments contained in milk have been the subject of many investigations. Some of them, such as pepsin, trypsin, lipase, the glycolytic ferment, the oxydases, and the anaëro-oxydases, are common to the milk of all the mammalia, while others, such as the amylolytic ferment and the ferment which attacks salol, are present in human milk but not in that of the cow. The importance of these ferments from the dietetic point of view has given rise to long discussions among those who advocate respectively either raw milk (*lait cru*) or sterilised milk for the feeding of new-born infants. The practical results observed in the use of sterilised milk deprived of its ferments seem to show that the latter are of only secondary importance when the milk is introduced into the digestive tract. The case, is however, quite different when the milk is converted into lacto-serum which is injected under the skin, the specific action of the ferments being now very pronounced. If the lacto-serum has been sterilised by heat there may be some increase in the amount of urine, but otherwise the effects are not very different from those of "artificial serum," whilst the injection of lacto-serum sterilised without heat is followed by some novel consequences. At first there is a slight rise of temperature coming on soon after the injection and lasting only a few hours. In the next place there is an increase in the polynuclear leucocytes, while there is often a remarkable increase in the excretion of uric acid, especially in febrile cases; finally, as a distinctive and peculiar phenomenon—for those just enumerated belong in common to almost all serums—there is a notable lowering (or what might more correctly be called a "regularisation") of the blood pressure in the arteries and capillaries. This phenomenon is novel and could not have been foreseen, because analysis of the lacto-serum does not reveal the presence of any substance capable of producing such an effect. Neither the very small amount of milk sugar contained in the 10 cubic centimetres which I gave as a dose, nor the trifling increase in the amount of urine which might be attributed to it, could be considered as the cause. There is, however, no doubt as to the fact, for a considerable number of observations both on the human subject and on the lower animals have enabled me to prove that when the blood pressure is increased, either from pathological conditions or artificially, injections of lacto-serum will cause the pressure to fall to normal more or less quickly and to remain at that level for a time. In cases of hypotension the blood pressure is not further reduced but has rather a slight tendency to rise. A case observed in the wards of Professor Robin, the patient being a female suffering from tuberculosis whose blood pressure measured by Verdin's apparatus fell to practically seven millimetres of mercury, is absolutely conclusive in this respect.

In some experiments made in the laboratory of Professor Richet in July, 1902, the arterial pressure in a dog was artificially raised by means of extract of suprarenal capsules, this being followed by an injection of cocaine for the purpose of prolonging the artificial rise of pressure which would otherwise be of short duration. I then found that the injection of lacto-serum brought down the pressure to the normal either quickly or at least in a much shorter time than would have been required for a spontaneous return to the normal without the administration of lacto-serum. Similar results were obtained in the human subject. In a patient whose radial artery showed a blood pressure reckoned in millimetres of mercury equivalent to 24, an injection of lacto-serum caused it to fall to 21, and sometimes to 20, in from three to four hours, the pressure rising again to 22 at the end of 24 hours. By means of a series of daily injections the pressure was brought down to the normal amount in six, eight, or ten days according to the nature of the cases, and a still more curious fact was that it remained normal for a month or more, whilst in one instance it remained normal for five months. Some cases resisted the treatment, but they were very few in number. It must also be remembered that the true cause of arterial hypertension is not as yet completely known, neither is it certain that the cause is always the same.

The therapeutical applications to which my inquiries led me have been as follows:—

1. *Puerperal infections.*—I made observations on four cases of this kind in the wards of which Dr. Maygrier has charge and on two cases in private practice. The results were variable, being sometimes successful and well marked, but at other times either uncertain or of short duration.

2. *Post-operative peritonitis.*—Three cases occurring in private practice were observed. The treatment was unsuccessful; there was an evident prolongation of the patients' resistance to the disease, but a fatal issue was not averted. In this condition the arterial tension is always low.

3. *Typhoid fever.*—Cases of this disease were observed in the wards under the charge of Professor Robin. In one there was a remarkable result, but of doubtful interpretation; in three cases there was no result.

4. *Pneumonia.*—Observations were made on 12 patients in the wards under the charge of Professor Robin and Dr. Maygrier. The results were in every way remarkable and constant. Defervescence always followed the second or even the first injection, sometimes on the fourth day of the treatment, the defervescence being as usual accompanied by an abundant excretion of uric acid. It must, however, be admitted that in pneumonia many kinds of serum give the same results as above described, and that the "metallic ferments" which came into prominence after my researches had been commenced produce even more remarkable effects. This merely proves the similarity of action of lacto-serum and of these ferments, a similarity on which Professor Robin has laid great stress in his important work on this subject.

5. *Arterial hypertension in arterio-sclerosis.*—It is in this condition that lacto-serum appears to me to find its most interesting application. My observations, 63 in number, were made upon patients in the wards under the charge of Professor Robin, M. Hachard, M. Oulmont, and M. Vaquez, as well as in private practice; ten have been described in communications received by me from brother practitioners. In one patient who was under the care of M. Vaquez and who received only a single injection the treatment was a complete failure. In almost all the others the fall of the blood pressure was constant and occurred under the conditions already detailed. Simultaneously with this fall of pressure there was a mitigation of the subjective symptoms such as headache, insomnia, general oppression, and shortness of breath on exertion. Every time that the treatment was applied according to the rules suggested by experience and continued for a sufficient period the results were surprising. There were at least 26 cases which I was able to keep under observation as private patients for a longer time than the hospital patients, because all the latter left the hospital as soon as they felt themselves better; these 26 cases showed a general improvement so well maintained as to amount to recovery, provided that from time to time the injections are repeated for several days as soon as signs of hypertension recur. Under these circumstances the patient is often free from symptoms for several months. All these patients resumed their ordinary course of life which had been interrupted by the illness, and some in opposition to my advice even discontinued the special *régime* which had been prescribed for them.

Several of the patients whom I treated had in their urine albumin, the amount of which was almost always slightly increased during the first days of the treatment. If there is [illegible] depends on hypertension [illegible] manently in patients who persevere with the treatment even though they discontinue the *régime* prescribed for them, but if there are renal lesions the albuminuria after the initial increase returns to its original amount. This supplies a convenient method of distinguishing between the albuminuria of hypertension and true organic albuminuria, serving in fact nearly the same purpose as the use of nitrites.

My ordinary method of administration is to give a daily injection of 10 cubic centimetres and to repeat it in 24 hours if the effect has not been sufficient until the blood pressure has fallen to normal. After this the injections are continued for four or five days longer, and then a weekly injection is given for a month, with more frequent repetitions if the pressure rises. When the pressure remains normal a monthly injection is given for three months. The injections are not repeated unless the symptoms of hypertension recur. The injection is made into the muscles of the thigh or of the gluteal region, or else under the skin of the flanks. Usually it is not painful; when pain is felt it shows that the serum has not been made isotonic in the process of preparation. Sometimes a little erythema is seen at the site of the puncture. No abscess has occurred in a total of more than 1000 injections.

The preparation of the lacto-serum is very simple. Milk as fresh as possible is warmed to 30° C. and rapidly coagulated by some drops of hydrochloric acid. The curd is removed by filtration through fine muslin and the liquid, after exact neutralisation with carbonate of sodium, is filtered through paper (*papier Chardin*); the final stage is filtration through a d'Arsonval bougie under pressure of carbonic acid gas. This filtration may be very tedious, for colloid substances liable to block the pores of the filter are sometimes present. This process introduces into the lacto-serum a little chloride of sodium which raises the natural low tonicity (*hypotonie naturelle*) of the liquid; it also introduces traces of peptone, appears to reduce somewhat the richness of the serum in oxydases, and leaves a small quantity of albuminoid substances which hinder filtration. Coagulation of the milk by means of some drops of rennet (*présure*), sterilised by filtration and with its action strengthened by a trace of chloride of calcium, produces a better curd, leaves no albuminous substances in the whey, does not form peptone, interferes less with the oxydases, and secures a more rapid filtration, but it requires the liquid to be made isotonic by the addition of a little chloride of sodium in order that the injection may not be painful. The lacto-serum is preserved in flasks (*ampoules*) hermetically sealed after being filled with carbonic acid gas. Under these conditions it may retain its activity for one month, two months, or even longer.

Boulevard Haussmann, Paris.

THE TREATMENT OF GRAVES'S DISEASE WITH THE MILK OF THYROIDLESS GOATS.

By WALTER EDMUNDS, M.A., M.C. Cantab.,
F.R.C.S. Eng.,
SURGEON TO THE PRINCE OF WALES'S HOSPITAL, TOTTENHAM.

Fifteen months ago a communication on this subject was made to The Lancet,[1] and three cases were recorded. Of the first of these nothing more has been heard; the second case was again treated with the milk during the whole of last summer down to the end of September, and the patient's medical attendant reports:—

> I last saw her on Nov. 10th, 1908, when she expressed herself as feeling well and able to do much more than she had been able to do previously; her pulse was 78 and her weight was 10 stones 1 pound (at one time her weight went down to 7 stones 9 pounds and her pulse could scarcely be counted, it was so rapid).

In the third case the patient continued to take the milk until Dec. 30th, 1907, when the supply failed. After this she was not quite so well, the pulse-rate increasing and there being some return of the œdema in the legs. Another goat came in milk in March, 1908, and the patient took the milk all last summer. Although the large goitre remained the same, yet the patient had very few subjective symptoms and but slight acceleration of pulse. The exophthalmos remained stationary. The supply of milk failed at the end of September, 1908, and the patient went to the seaside. Here she had a bad attack of gastro-intestinal disturbance with persistent vomiting and diarrhœa; since then she has been mainly in bed and subject to occasional severe attacks of palpitation and choking sensations at night. During the past two months the patient has been treated with dried blood from a thyroidless goat, five grains three times a day, but without improvement. Although milk is again available it cannot be taken on account of the gastric symptoms.

The following seven cases were under treatment at the Prince of Wales's Hospital, Tottenham, and I am indebted to the physicians under whose care they were for permission to publish them.

Case 4.—The patient was 19 years of age and unmarried. Her illness had commenced four years ago after some domestic trouble. The symptoms then were pain in the cardiac region and fulness of the throat and these symptoms continued. On admission to hospital there was found to be an obvious enlargement of the thyroid gland and the pulse-rate was 104. There was slight prominence of the eyes, slight tremors in the hands, and occasional attacks of a sense of suffocation in the chest, the patient's weight being 6 stones 12¾ pounds. She was treated with milk from a thyroidless goat and strophanthus and she improved and was able to leave the hospital in 41 days, having gained 5¾ pounds in weight. The pulse-rate remained about the same.

Case 5.—The patient was a married woman, aged 36 years. The illness had commenced four months before attendance with marked prominence of the eyes, neuralgia in the forehead and the face, enlargement of the thyroid, difficulty in swallowing, palpitation, shortness of breath, and increased appetite. When first seen there were present pronounced exophthalmos, enlargement of the thyroid, and marked tremors. At first the patient was treated as an out-patient with rodagen and under this treatment the exophthalmos diminished. After a month she was admitted to the hospital and was treated with milk from a thyroidless goat, about a pint and a half a day. In six weeks she was much improved and was able to go to the seaside, where she gained 11 pounds in weight, but the exophthalmos remained the same. On her return she again took the milk and continued to improve till December, when the supply failed. Ten days later the patient was much worse; she was weaker and more tremulous, and was suffering also from shortness of breath and from attacks of cardiac pain; she had not had any of these attacks since the early days of her illness. She was readmitted to hospital and was treated with thyroidectin and she has much improved.

Case 6.—The patient was a married woman, aged 36 years, and the mother of six children. The illness had commenced four years ago during pregnancy. On admission to hospital there were found to be severe palpitation, œdema of the legs, nervousness, with tremors in the hands, and enlargement of the thyroid, but there was no exophthalmos. The patient was treated with milk from a thyroidless goat and she improved, but she left too soon, to look after her children.

Case 7.—The patient was 20 years of age and unmarried. She had a large soft goitre giving a sense of pulsation and a well-marked thrill. There was distinct exophthalmos, and the pulse was 120; slight tremors with occasional attacks of shortness of breath were present. The patient was treated with milk from a thyroidless goat and she quickly became much better, leaving the hospital in 39 days.

Case 8.—The patient, aged 20 years, unmarried, had had appendicitis six months ago, for which she was operated upon. Three months later there were symptoms of gastric ulcer with vomiting of blood and the present symptoms followed. On admission to hospital the patient was markedly pale and the pulse was 144; the thyroid gland was felt on examination to be enlarged and there was shortness of breath, but no exophthalmos was present. The treatment consisted of milk from a thyroidless goat and under it the patient improved greatly.

Case 9.—The patient was 17 years of age and unmarried. On admission there was distinct enlargement of the thyroid gland, with tremors of the hands and anæmia, but there was no exophthalmos. This was a mild case. The patient quickly improved under the milk treatment, only remaining in hospital 20 days. The pulse on admission was 104 and on leaving it was 80.

Case 10.—The patient was a married woman, aged 29 years, and the mother of four children. On admission to hospital there were present marked exophthalmos, nervousness, with constant movement of some part of the body, headache and giddiness, enlargement of the thyroid, and a systolic murmur at the apex. Treatment with milk from a thyroidless goat brought about an improvement, but the patient left too soon, in order to look after her children. 15 months later she attended the out-patient department for a time with all the symptoms of the disease well marked.

Case 11.—Treated in the country. The patient was a married woman, aged 32 years, who had suffered from the disease for four years. The symptoms were palpitation, a pulse-rate of 130, fulness of the throat, with pulsation of the thyroid gland, and slight exophthalmos. She was treated with the milk of a thyroidless goat and in three weeks' time was better.

---

[1] The Lancet, Jan. 25th, 1908, p. 227.

Some of the milk was sent to St. Thomas's Hospital, where Dr. Hector W. G. Mackenzie kindly tried it on the following four cases.

CASE 12.—The patient was an unmarried woman, aged 21 years. The illness had commenced 17 months ago with swollen neck, tremors, and prominence of the eyes. On admission to hospital the patient was very thin and considerable exophthalmos was present. The thyroid gland was slightly enlarged; there were tremors in the hands, the pulse-rate was 160, and the patient's weight was 5 stones 8 pounds. She was ordered 35 ounces of the milk a day and she gradually gained in strength and in weight, the gain in the latter respect being 1 stone 2 pounds.

CASE 13.—The patient, aged 20 years, was unmarried. Two years previously to coming for treatment she had been an in-patient for eight months with marked exophthalmos, tremors of the hands, and a systolic murmur. She was treated with rodagen and x rays to the thyroid and she got much better and gained 2 stones in weight. She was kept under observation and was readmitted a year later. All the symptoms of Graves's disease were well marked. She was treated with the milk from thyroidless goats and improved, gaining several pounds in weight and the pulse-rate falling.

CASE 14.—The patient was 20 years of age and unmarried. On admission there was enlargement of the thyroid gland with a thrill and the pulse-rate was 120. There were tremors in the hands but no exophthalmos was present. She was treated with milk from a thyroidless goat, about a pint a day. She steadily improved, leaving in 34 days, and having gained 1 stone 3 pounds in weight, the hands being much less tremulous and the pulse-rate remaining about the same.

CASE 15.—The patient, an unmarried woman, aged 42 years, had suffered from Graves's disease for 14 years. Two years ago she had been an in-patient for ten months and had improved somewhat, but became worse again after returning home. She was readmitted and was treated with milk from thyroidless goats, but did not improve under the treatment.

It is satisfactory that none of the patients treated have so far died. It is not always so. On looking through the reports of one large hospital it is seen that there were in ten years five deaths, and at another hospital in the same time 11 deaths. Only two of the cases did not improve under the treatment (*Cases 3 and 15*), but the patient in Case 3 did improve while the milk could be given, and the condition in Case 15 was of long standing. It is, of course, possible that the improvement may have been due wholly, as no doubt it was in part, to the rest and good diet obtained in hospital, but the patient in Case 1 continued to lose ground under these conditions till the milk was given. Cases 2 and 11 were treated wholly at home, and in Cases 3 and 5 the patients became worse when the milk had to be stopped. Further, Dr. A. Gordon Gullan has reported good results from rodagen and thyroidectin.[2]

As the anti-body in the milk must be derived from the blood serum it would seem better to administer the dried serum and corpuscles from a thyroidless animal. But there is one point in favour of the milk: ordinary cow's milk must contain a certain amount of thyroid secretion, therefore we have either to give this or to cut ourselves off from an article of diet valuable for invalids: the use of milk from thyroidless animals relieves us from this dilemma. The reduction in the amount of thyroid secretion in the patient can also be brought about by the excision of part of the enlarged thyroid, and several surgeons have recently reported successful cases of this treatment. The operation has, however, been attended with a heavy mortality in the past; but in one case in which the patient was seriously ill with the usual symptoms, including paroxysmal attacks of palpitation and dyspnœa, I removed the major part of the goitre and the patient was speedily and greatly benefited.[3] If an operation is to be undertaken it should not be delayed until the patient is materially weakened by the disease. It is true that a certain number of cases recover under medical treatment, but what we have to avoid is not so much unnecessary operations as unnecessary deaths. Even if operation is the best treatment for the majority of cases we still require a medical treatment for the cases which are too mild for operation, for those patients who are too ill for operation, for those who decline operation, and for those cases which have been operated upon but which have not been completely cured.

Devonshire-place, W.

RADIOGRAPHY AS AN AID TO THE DIAGNOSIS OF DISEASES AND INJURIES OF THE SKULL AND BRAIN.

BY ROBERT KNOX, M.D. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.,

MEDICAL OFFICER IN CHARGE OF ELECTRICAL DEPARTMENT, GREAT NORTHERN CENTRAL HOSPITAL.

WIDE as are the applications of the Roentgen rays in the diagnosis of disease no more interesting field of investigation exists than that which comprises the subject stated above. This method of demonstration in relation to these diseases and injuries is of great importance. A radiographer should be a trained clinical observer and not merely a taker of radiographs, for on the correct interpretation of what one actually sees depends very largely the value of diagnosis by radiography. When Professor Roentgen first announced his great discovery medical men were eager to avai [illegible] new aid to diagnos [illegible] could be applied [illegible] the direction of [illegible] of foreign bodies in the walls of the skull and cranial cavity the value of the new aid to diagnosis was great. Improved methods of application and instrumentation led to more accurate results until at the present time it is possible to show many lesions and injuries in the skull and its adjacent parts and in the brain itself. The position of foreign bodies can be clearly shown, fractures of the skull can be located, abscess of the brain should give a definite shadow, and the correct location and size may be shown in the skiagram. Tumours of the brain are also capable of being demonstrated; those which are attached to or have their origin in the bony walls or periosteum of the skull are readily recognised. The nature and consistence of cranial tumours determine the degree of the shadow which they are likely to give. A tumour having the same consistence as the brain tissue will not give a definite shadow, but a tumour of greater density than brain tissue should be capable of demonstration. In radiography of other parts of the body one has to show bones in relation to soft parts and, as a rule, [illegible] in cranial radiography there [illegible] of dealing with a bony case consisting of two more or less thick walls with a space of several inches between. The early radiographs show merely an outline of the skull as a whole, with shadows of varying density which might or might not be capable of interpretation. Later efforts have been more successful in showing the various component parts of the bony skull and the contents of the cranial cavity.

In order to get a good radiograph of the skull and its contents it is necessary to use a fairly powerful coil and to vary the exposure according to the amount of current used. Most of the coils in use at the present time give a large output of energy and if one can get a tube with a sufficient degree of penetration the demonstration of the skull and its contents is made comparatively easy. An x ray tube with a spark gap of five or six inches is capable of penetrating the average skull. The time exposure will vary with the thickness of the subject and the rapidity of the photographic plate in use. Several of the skiagrams taken have been done with a portable apparatus and others with powerful stationary installations. The exposure varies from five seconds to five minutes and good results have been obtained with various exposures between those limits. Recently it has been possible to get good detail with even shorter exposures than five seconds, and no doubt in time an exposure of a fraction of a second may be sufficient to overcome the resistance of the parts and yield good results.

The chief advantage of a short exposure lies in the fact that movements are reduced to a minimum and the resulting shadow is more clearly defined in consequence. While this is of great value in the radiography of regions of the body where movement is constantly going on, such as in the lungs and heart, it naturally has not the same importance in the case of the skull, where we have a rigid bony case to deal with. Yet no doubt even here short exposures will yield better results.

---

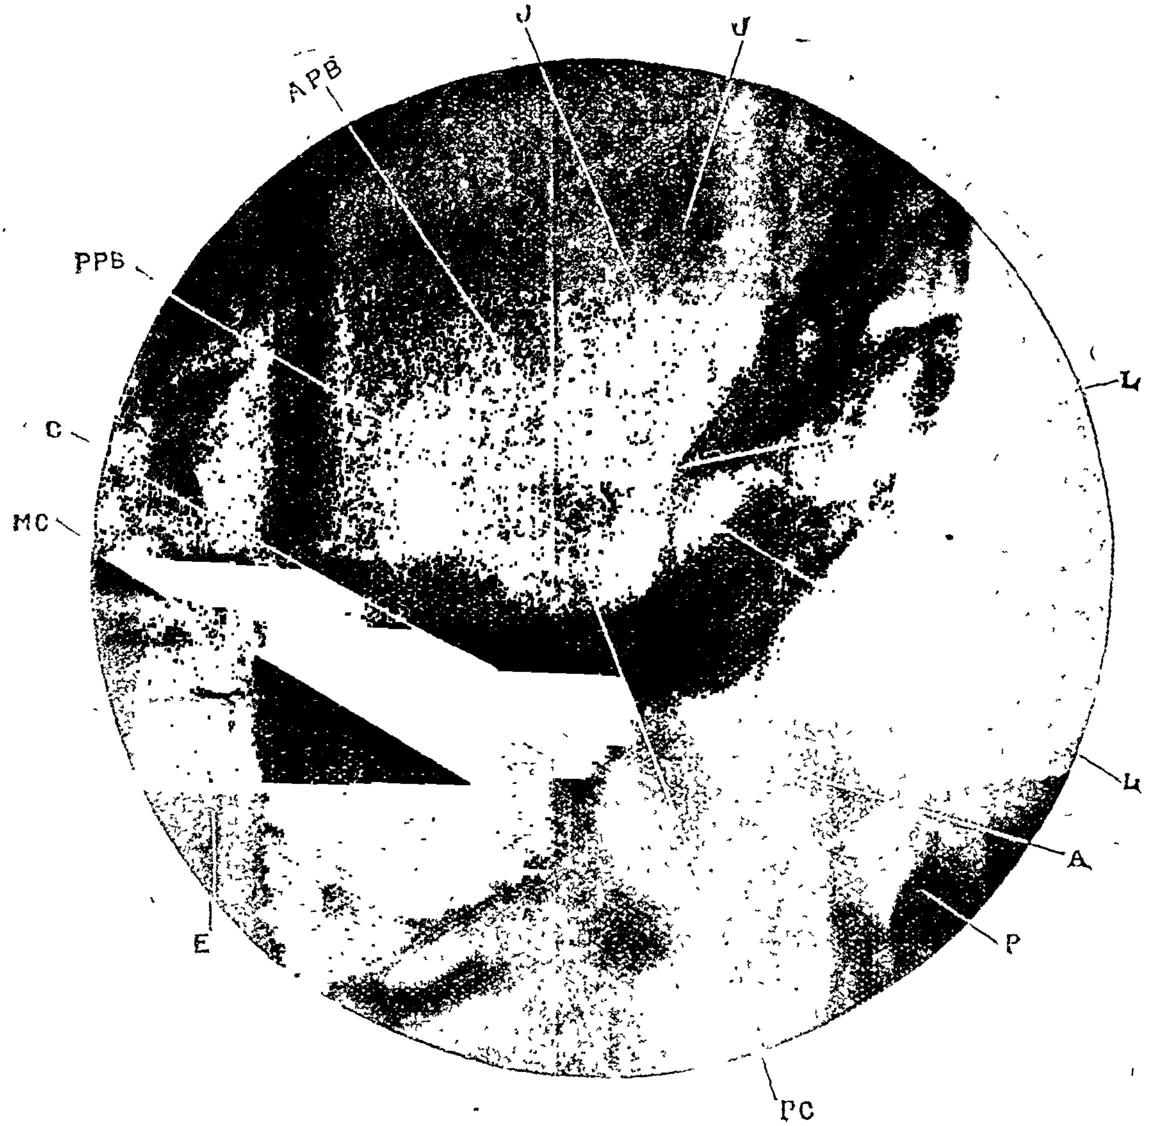
[2] THE LANCET, Sept. 5th, 1908, p. 708.

[3] Journal of Pathology and Bacteriology, vol. iii, 1896.

Quite recently the exposure time has been cut down to fractions of a second. This has been achieved by means of Wehnalt breaks and a special time switch which automatically cuts off the current at the proper moment. The radiographs so produced are remarkable for the clear definition of the parts taken, and one can readily understand why this should be so. The exposure is shortened by increasing to an enormous extent the amount of current passed through a tube. The tube will stand the strong current only for a short time, but sufficiently long to enable the rays to penetrate the thickest portions of the body and give good results. The important point about the new development lies in the very short duration of the exposure and the consequent elimination of the effects of voluntary and involuntary movements on the part of the subject. In the case of children this is a very important factor in the obtaining of good radiographs. Another advantage is that the patient can be placed at a greater distance than at present. At about six feet from the anode of the tube a shadow can be obtained which accurately represents the size of the organ radiographed. In heart work this promises to be extremely useful and the result will probably be that orthodiagraphy will be largely superseded by the new method.

In order to appreciate and demonstrate the existence of abnormalities it is necessary to be familiar with the normal appearances of the parts under consideration. The skiagram shown below, represented in *Fig. 1* (a reproduction of a radiograph of a normal skull showing the principal bony points), was taken from a normal subject and an examination of its details will show the chief bony points which it is necessary to note for comparison when considering possible abnormalities.

FIG. 1



Skiagram of a normal head, showing appearances at the base of the brain. Note especially the two portions of the pituitary body, the anterior portion being situated in the sella turcica (APB) and the posterior portion behind it (PPB). A, Condyle of lower jaw. P, Artificial plate in upper jaw. PC, Posterior clinoid process. F, Cerebellum. MC, Mastoid air cells. C, Petrous part of temporal bone. J, Groove for blood-vessels. L, Anterior clinoid process.

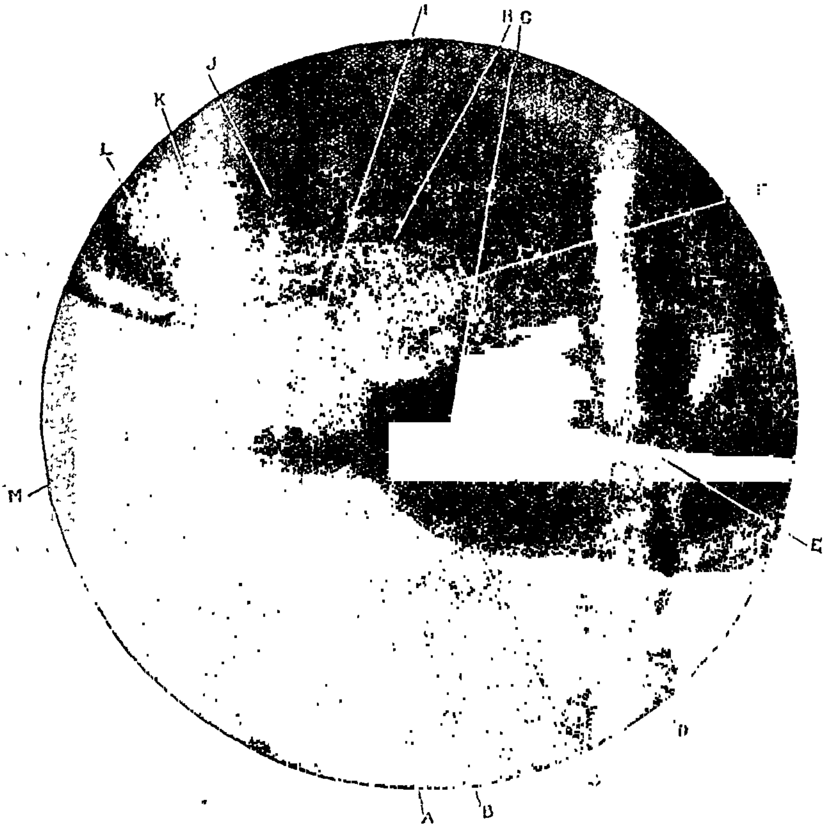
The points to observe are the levels of the base of skull in relation to the exterior, the clinoid processes the sella turcica between, the relations of the chief to the various levels, and the well-marked grooves in inner table of the skull for blood vessels. A clearly shadow is thrown by the pituitary body situated in sella turcica. The three levels of the base of the skull well shown. This radiograph was taken with a intensified induction coil by Watsons and a Mote break on a voltage of 240. The tube used was a anode by Muller and the equivalent spark gap was inches. The exposure was a long one of about minutes. A simple diaphragm compressor was used to econdary radiations. An Ilford special x ray plate was [illegible] The developer was pyro soda. The development of plate took half an hour.

ig. 2 shows the appearance of the skull in a case of bral tumour: a chiasma lesion of fairly large size. The ogram which it represents was taken with a diaphragm veen the tube and the subject to cut off secondary ations. The case was sent to me by Dr. W. Mailer of well-hill, and Dr. Purves Stewart has kindly supplied me the following particulars:—

> e patient was a man, aged 35 years, who complained of persistent siness of several months' duration. A month before coming under the whole skull and showed an obscuration of detail in the region of the sella turcica. It was noticed that the anterior clinoid processes were barely perceptible while the posterior were *obliterated.*

The appearances seen in the skiagram can be interpreted as follows: A well-defined shadow occupies the sella turcica and extends backwards to the posterior limit of the petrous temporal bone; it is of varying density, having light and dark areas in its midst. The anterior clinoid processes are ill defined and appear to be spread out laterally. The posterior processes are not to be seen. The shadow of the tumour fades away into the brain substance.

FIG. 2.



Sk[illegible] Note obliteration of definition of sella turcica. A, Condyle of lower jaw. [illegible] process of vertebra F, Cerebellum. F, Shadow of tumour. G, Petrous [illegible] umour. I, Lower limit of shadow of tumour. J, Groove for blood vessel.

[illegible]

in.

The x ray examination of this case was particularly in-uctive. [illegible] which was unded an [illegible] had well-veloped c [illegible] included

The examination of the brain offers the greatest difficulties in the Roentgen diagnosis of diseases. Dr. Paul Regnier and Jules Gloner have published a paper on this subject which is full of useful information. Dr. D. Walsh summarises their results as follows:—

> Their main conclusions are that it is possible to superimpose upon the [illegible] outline of the cranial sutures and of the cerebral [illegible] eral ventricle can be [illegible] of the lateral sinus, [illegible] nd the adult. The [illegible] y cells of the bony sinuses can be studied The exact position of the three levels of the base of the skull can be ascertained with regard to the outer skull.

The exposures they gave were long ones, from 10 to 40 minutes. Such exposures are not safe in the living subject. None of the exposures in the cases quoted in this paper exceeded four minutes. Good results can be obtained with an exposure of five seconds and in view of the recent developments one is safe to predict that in the future it will be possible to get a good radiograph from the living subject with a second's exposure and possibly with one of a tenth of a second. The advantages of such a short exposure cannot be over-estimated. With such short exposures it will be possible to clearly outline the bony points of the skull, the grooves for the blood-vessels in the walls of the skull, and possibly the outlines of the chief parts of the brain. Abscesses in the brain might be shown, and it might even be possible to locate hæmorrhage of any considerable size. Tumours are capable of being demonstrated and located. The aid to diagnosis and localisation of such tumours will be great.

Dr. Walsh, in his book "The Röntgen Rays in Medical Work," quotes several interesting cases by various workers and describes methods for the localisation of foreign bodies in the brain. By a simple method which he describes it is, as he says, possible to locate with the tube in two positions by bringing an opaque object into line with the foreign body and then marking the entry and exit of that line on both sides of the skull, the point of intersection being the site of the foreign body. In a case of bullet in the brain a rough method of localisation was adopted by me to which I will refer. A thin piece of wire was placed around the head as nearly as possible in line with the lower and outer angles of the orbits and the mastoid processes. Another piece was carried over the vertex of the skull in line with the anterior edges of the auricles. The patient was then placed on his side with the plate underneath his head, and a radiograph was obtained in this position. The position was then reversed and one taken from the opposite side. A third negative was obtained in the antero-posterior position. On comparing the three plates it was seen that a large fragment of the bullet was lodged in the occipital region immediately underneath the bone and on the right side of the brain. The surgeon who operated on this case was able to locate the bullet accurately and made his trephine wounds in the skull in such a position that when the bone was removed the portion of bullet could be felt with a probe in the position indicated by the radiographs. An instrument capable of being adjusted to fit the skull of any individual could readily be devised of such a nature that the various portions of the skull and brain could be divided into sections and when used in radiography would show where a foreign body was situated.

In a case of a foreign body in the right eyeball we were able to see from the radiograph that the fragment of steel was clearly in the eyeball and from its size it was evident that the function of the organ must necessarily have been destroyed. The eyeball and foreign body were removed by operation. For purposes of localising foreign bodies in the eyeball Dr. J. Mackenzie Davidson has devised a useful apparatus which should be applied in all cases where doubt exists as to the exact position of a foreign body in the orbit. The importance of determining whether a foreign body is in the eyeball or in the orbit is, of course, obvious, and careful radiographic examination should be made in all such cases before an operation is decided upon.

The examination of the ear by radiography may be helpful in cases of disease. Abscesses in the mastoid region should be capable of demonstration. The frontal sinuses and antrum can be examined by taking negatives in various positions, and, where possible, a probe passed into these cavities before the radiograph is taken will help to clear up the diagnosis in diseases of those parts.

Shepherd's hill, N.

SHREWSBURY EYE HOSPITAL.—At the annual meeting of the Shrewsbury Eye, Ear, and Throat Hospital, an institution which was established as long ago as 1818, the honorary ophthalmic surgeon, Mr. C. G. Russ Wood, commented on the large increase in the number of children who required spectacles. The increase is, no doubt, more apparent than real and is due to the inspection of school children which is being carried out in Shropshire and the adjoining Welsh counties from which the patients of the hospital are drawn. During the past year an entirely new system of drainage has been carried out at the hospital and a new out-patient operating theatre has been erected. In spite of the unusual expenditure thus entailed the balance-sheet was a satisfactory one.

SOME REMARKS ON TUBERCULIN THERAPY.

BY A. J. LANDMAN, M.D., CH.B. VICT.,
LATE HOUSE PHYSICIAN, GENERAL INFIRMARY, LEEDS, AND RESIDENT MEDICAL OFFICER, IDA AND ROBERT ARTHINGTON HOSPITALS, COOKRIDGE.

THE growth and increasing importance of vaccine therapy at the present time is generally recognised. The opsonic method of Wright has established this mode of treatment on a scientific basis. The brilliant results obtained by this treatment in staphylococcic infections have led to the hope that equally good results might be obtained in other infections. Thus the vaccine treatment of tuberculosis originally introduced by Koch has again been brought into prominence, and tuberculin, which had fallen into disrepute, was again taken up as a curative agent. Administered according to the principles laid down by Wright, tuberculin has proved free from the dangers formerly associated with it, and in many cases good results have been obtained. While the final verdict cannot yet be given as to its efficacy it may be said that the results obtained have been encouraging.

Since the introduction of tuberculin by Koch[1] about 17 years ago for the curative treatment of tuberculous disease there have been marked fluctuations in its popularity in the medical world. It was received with enthusiasm and subjected to extensive clinical trials. But it was not destined to fulfil the hopes entertained of its utility. Many observers reported that it was a dangerous remedy and it soon fell into disrepute. The report of the Brompton Hospital for Consumption, 1892, stated that tuberculin did not favourably influence the course of the disease in the majority of cases. [illegible] was probably excessive. It proved [illegible] reasons. The doses recommended by Koch were too high, and it was used in unsuitable cases. But the fact remained that it was practically abandoned as an agent, if not positively harmful, at least incapable of effecting the good claimed for it. It was no longer looked upon as a curative agent, but the febrile reaction which it produced in a tuberculous individual was regarded as of value in diagnosis. In veterinary practice it has found a permanent value as a means of recognising concealed tuberculosis, and recently Calmette, Wolff-Eisner, and von Pirquet have utilised it successfully for human diagnosis.

The dangers associated with the administration of old tuberculin led Koch and his pupils to continue their researches in order to produce a safer tuberculin. In 1897 Koch[2] announced that he had prepared a new tuberculin which retained the curative and immunising power of the old one, but did not produce any dangerous febrile reaction, and no ill-consequence resulted from its use in tuberculous cases. The dose recommended by Koch was 1-500th milligramme, gradually increased to 20 milligrammes. The introduction of the new tuberculin T.R. caused some renewal of interest in the subject for a time, but in England it did not seem to gain any general hold.

Recently Koch has introduced a new tuberculin B.E. (Bacillen-Emulsion). Assuming that tuberculin acts in the same way as the other vaccines, the preparation B.E. should prove the most satisfactory of all the tuberculins. During the last few years there has been a considerable revival of interest in the tuberculin treatment. This has been due in England chiefly to the researches of Wright on opsonins and the application of his opsonic index determinations to the treatment placing it in a line with the treatment by other vaccines. But it must not be forgotten that many physicians have continued to use tuberculin ever since its introduction quite independently of Wright's work on the subject. The detailed method associated with Wright's name for the determination of the opsonic index is not an essential part of the therapeutic application of tuberculin. Previously the tuberculin treatment has been regulated by other clinical signs, including pulse, temperature, patient's aspect, local symptoms and signs, and prolonged experience justifies the statement that these clinical signs will suffice, apart from opsonic index determinations. The complexity of the technique of Wright's method is also an insurmountable difficulty in many cases, and detracts greatly from its general utility. The margin of error in such a complicated process must necessarily be considerable, and this fact must also be taken into consideration in estimating the practical value of opsonic index determinations. The question of the utility of the method in practice must therefore still remain an open one. Wright's work, however, has given a fresh start to the active immunisation method of the treatment of tuberculosis, and what we particularly owe to Wright is the demonstration that small doses of tuberculin are effectual and that large ones are unnecessary. The peculiar action of the tubercle bacillus, as shown by the slowness and chronicity of the lesions which it produces, the tendency to spontaneous healing of tuberculous foci by caseation and encapsulation, place this organism on a somewhat different footing from the other organisms as regards the process of immunisation, and the dosage of tuberculin may differ from that of the other vaccines. There is little doubt, however, that in certain cases of localised tuberculosis, such as lupus, tuberculous joints, glands, and genito-urinary tuberculosis, improvement has followed the use of tuberculin according to Wright's method.

---

[1] R. Koch Mittheilung [illegible] d Tuberkulose. Deutsche Medicinische [illegible] Mittheilungen uber das Tuberkulin, ibid [illegible] nd, 1891.

[2] Deutsche Medicinische Wochenschrift, April 1st, 1897.

Further study will be necessary before the exact nature of opsonin and opsonic action is fully understood. The opsonic theory attempts to explain the action of vaccines by their stimulation of the immunising machinery of the body to the increased formation of opsonin. Wright holds that the practical application of the opsonic theory, as shown by the method which he has described of estimating the opsonic index, enables us to follow the successive phases of immunisation, and we can step in and assist the process at appropriate times by injections of vaccines. By estimating the opsonic index in cases of tuberculosis he was able to observe the variations in the amount of opsonin present as shown by what he called the positive and negative phases. From these variations he deduced that in an untreated tuberculous individual spontaneous auto-inoculations occur from time to time which follow a certain cyclic periodicity. The negative phase, or the period of low opsonic index, shows that there has been an outpouring of either tubercle bacilli or their products of metabolism into the system from the tuberculous focus and this has used up most of the opsonin present. The positive phase which followed the negative was due to the increased production of opsonin, owing to the stimulation of the machinery of immunisation by the bacilli and their products. He also showed that these auto-inoculations could be influenced by artificial means; thus, by massage of a tuberculous knee he brought about a negative phase due to the increased outpouring of bacilli and their products. He utilised such artificial auto-inoculations as an aid to diagnosis. To take the same example, the diagnosis of a certain chronic knee affection was required. The opsonic index was taken, massage or passive movement was performed, and the opsonic index again estimated. The second estimation showed a lower index than the first. The joint was therefore tuberculous. He also showed that the administration of tuberculin acted in a similar way to spontaneous or artificial auto-inoculations. A dose of tuberculin was followed by a negative phase. Opsonin was used up for coping with the inoculum. This provoked a fresh production of opsonin in increased amount and was therefore succeeded by a positive phase. The process of immunisation could thus be regulated by appropriate doses of tuberculin at suitable intervals, the aim of the injections being to get the index to oscillate within normal limits as in a healthy individual. Clinically the negative phase coincided with a feeling of illness, the temperature perhaps was raised, and the pulse accelerated. On the other hand, during a positive phase the patient felt better and brighter. Wright[3] showed that the amount of opsonin in the serum also corresponded with the amount of other immunising substances. He tested this by measuring the agglutinative power of the blood of a guinea-pig, which was subjected to inoculations of glanders bacilli sterilised by heat. The amount of agglutinin in the blood showed positive and negative phases similar to those in opsonic estimations. The course of the immunising reaction could be followed either by measuring the amount of opsonin or the amount of agglutinin present in the blood. By estimating the opsonic index, therefore, from time to time we are enabled to gauge the progress of immunisation and to help it on when necessary by inoculation of tuberculin.

The technique of opsonic index determinations is far too complicated. If we are to carry out the treatment properly very frequent estimations of the index are necessary, and the variations due to spontaneous and artificial auto-inoculations must be taken into account or eliminated. As Wright himself has pointed out, spontaneous auto-inoculations affecting the opsonic index are of constant occurrence, the result of exercise, excitement, and various other factors, and the question may well be asked whether even daily estimations of the opsonic index which is subject to such frequent changes can afford any reliable guide to the progress of immunisation. Some observers have attempted to simplify the technique. Thus Simon,[4] working with the staphylococcus, states that he has secured results strictly comparable with Wright's opsonic (bacillary) index by comparing the number of leucocytes which show phagocytosis with those that do not (percentage index). To perform this it is necessary to use such a thin emulsion that at least 50 per cent. of the leucocytes do not contain any organisms. This method renders the counting much less laborious, but it is open to the objection that the serum, having the higher value in opsonin, does not meet with a sufficient number of bacilli to enable it to show its full opsonic power, and an experimental error is thereby introduced. The present tendency is to seek some other reliable guide to the administration of tuberculin than opsonic index determinations, and the researches that are being carried out at the present time have been undertaken with that object. Thus the recent work of Dr. A. Latham and Dr. A. C. Inman[5] has thrown valuable light on the dosage and mode of administration of tuberculin, based on observations of the temperature and clinical condition of the patient, combined with simultaneous observations of the opsonic index. Wright's method has, however, been of undoubted value in giving a great stimulus to vaccine and tuberculin therapy and placing this mode of treatment on a scientific basis, replacing the former empiricism and uncertainty of dosage by some degree of precision.

The following cases were under my care at the Ida and Robert Arthington Hospitals whilst I was resident medical officer there, and I am indebted to Mr. Harold Collinson, honorary surgeon to the hospitals, for granting me the necessary facilities for carrying out the tuberculin treatment. The opsonic estimations were undertaken by myself, with the assistance of Dr. O. C. Gruner, pathologist to the Leeds Infirmary. In all cases the tuberculin treatment was carried out in addition to the ordinary remedial measures. (The hospitals are so constructed that patients can undergo open-air treatment as in a sanatorium.) No special selection was made in the cases for treatment, and it was therefore tried in various conditions of advanced and early phthisis, glandular and bone tuberculosis. The injections were given in the flanks, using an all-glass syringe, and the patients remained in bed for 24 hours after each injection to eliminate as far as possible any spontaneous auto-inoculations. As regards the technique employed for estimating the opsonic index, the only modifications from that described by Wright were, that instead of taking equal quantities of the three constituents—viz., emulsion of tubercle bacilli, leucocytes, and serum—it was found better to use equal quantities of emulsion and serum with twice the quantity of leucocytes. The controls were made with my own serum which was previously compared with Dr. Gruner's and found to give about the same index. In order to minimise the experimental error as far as possible, the opsonic index of a second healthy person's blood was taken in many cases and the mean of the two used as a standard. It was also found that if a long series of "bloods" were examined on any one occasion, the last two or three always gave an unduly low opsonic index. It is known that the opsonic power of the serum diminishes gradually after it has been withdrawn from the body, and this may be the explanation of the above fact. In order to avoid this error it is advisable not to test more than six bloods on any one occasion, and all the specimens should be obtained within a

) no

The results cannot be said to show anything conclusive. Several cases seemed to derive benefit from the tuberculin inoculations. The injections raised the opsonic index in several cases but the negative phase was not at all constant It is difficult to say whether the favourable results observed might not have been due to the open-air treatment alone. No harmful results were noticed after the inoculations, except in one case. This patient, aged 20 years, was an in-patient at the Robert Arthington Hospital six months previously for tuberculous disease of a rib and had received three or four inoculations of the tuberculin in the left forearm. She was discharged cured. In August, 1907, she was re-admitted with a tuberculous abscess of the left forearm which had developed at the site of the inoculations. The abscess was opened and scraped and soon healed. No further injections of tuberculin were given The formation of an abscess was probably due to the presence of living bacilli in the tuberculin used.

Gower-street, W.C.

THE

CEREBRO-SPINAL FLUID IN GENERAL PARALYSIS AND THE NERVOUS LUES.

BY G. S. WILLIAMSON, L R C.P. & S. EDIN.,
ASSISTANT DIRECTOR OF THE CLINICAL RESEARCH ASSOCIATION.

IN the light of Dr. F. W. Mott's *Morison lectures* the following research, conducted during the winter of 1907-08 at Greenock Poorhouse and Asylum, ought to prove of interest. A small amount of normal citrate solution was taken up in the syringe and ejected as the needle penetrated the tissue; in this way *little or no blood was drawn into the* syringe with the fluid, and the amount of citrate in the fluid

pecific gravity.

were reserved

quantity being used for cultural tests. In the post-mortem cases the ventricles were tapped before the brain was exposed and the cerebro-spinal fluid withdrawn, as in life. The cultural tests were undertaken with the view of testing Dr. W. Ford Robertson's hypothesis for general paralysis of the insane. The appended table gives the results of the chemical examination.

In making a count of the cells, 5 cubic centimetres of fluid were centrifugalised at high speed, the supernatant fluid poured off, and the deposit shaken up in ½ cubic centi-

ces of formalin

the cells en-

The fluid of the general paralytics differs from the normal in having a high *specific gravity and containing nucleo-*proteid, in having a high count of cellular elements, and in giving a precipitate with butyric acid, according to Noguchi's method. The only case which gave a negative result was *one of some years' standing* and suffering at the time from profound melancholia. In the three cases in which the Wassermann test was applied a positive result was obtained and confirmatory to the Noguchi test. The cases of tabes dorsalis were uniform in containing nucleo-proteid in their cerebro spinal fluid. Three out of five gave a Noguchi

precipitate. The tabo-paralytics, three in number, were selected for a Wassermann test; one out of the three gave a positive reaction and was also the only one to give a precipitate by Noguchi's method. Four cases of general paralysis, all the cases of tabes dorsalis, the cerebral syphilis, and the syphilitic cases had undoubted evidences of syphilis, and all gave the Noguchi reaction. It is noteworthy that one case of pernicious anæmia gave the Noguchi reaction and also Wassermann's reaction, although no history of syphilis could be obtained. In the seven cases in which Wassermann's reaction could be done the result confirmed the Noguchi reaction.

These facts are significant, but, of course, with only a small number of cases there is no justification for dogma.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A CASE OF HYDATID DISEASE OF LUMBAR VERTEBRA.

BY A. F. THEOBALDS, M.B., CH.B. EDIN.,
RESIDENT ASSISTANT MEDICAL OFFICER TO ST. LUKE'S HOSPITAL, SALTERHEBBLE, HALIFAX; LATE PATHOLOGIST AND ASSISTANT MEDICAL OFFICER TO THE WEST RIDING ASYLUM, WAKEFIELD.

HYDATID disease of bone is a somewhat rare condition and the following case is of interest both from the advanced age of the patient and the prolonged duration of the disease.

The patient was an inmate of the West Riding Asylum and was 75 years of age. He had been admitted six years previously from the workhouse and nothing was known of him or of his previous life. It is interesting to note that on admission two small scars were observed over the sacrum which he said were due to an abscess which had been opened, and into which he maintained "13 worms had been put," this remaining one of his fixed delusions. His general health appeared to be very good at this time and it was only about seven months before his death that symptoms of spinal disease showed themselves, the patient becoming paralysed in the lower limbs. The reflexes were lost and both the bladder and the bowel were involved, and the small fluctuating tumour was noticed in the right lumbar region.

The post-mortem examination was made 20 hours after death. The body was emaciated and the lower limbs showed considerable wasting and some contracture. A soft fluctuating tumour of about the size of an orange was present in the right lumbar region and a distinct want of continuity was felt in the spine at its lower end, and there was a slight abrasion of the skin over the sacrum. On incising the tumour it was found to be a suppurating hydatid cyst and about a pint of fluid was evacuated containing numerous daughter cysts varying in size from that of a grape downwards. The cyst was thick-walled and it consisted of two cavities, the upper one extending upwards as far as the second lumbar vertebra on the right side and compressing the muscles, and the lower one somewhat to the left of the sacrum between the ilium and the pelvic muscles, quite extraperitoneal but bulging into the abdominal cavity and forming a somewhat prominent tumour. The cavities communicated with each other, and on further investigation the body of the fifth lumbar vertebra was found to be quite carious, great destruction of bone having taken place, causing fracture of the spine. No new bone formation was seen. The lumbar vertebræ were removed, the fourth and fifth alone being involved. Tiny cysts were seen infiltrating the bone and had penetrated and lacerated the periosteum, the vessels of which were much injected. The membranes of the cord appeared to be healthy, but a few cysts were seen in the cauda equina. The right iliac crest was also carious, evidently from pressure, as no cysts were seen. No other cysts were found in the brain or other organs. There were evidences of cystitis and an ascending pyelitis and slight atheroma of the aorta.

On microscopical examination of the cysts numerou scolices and hooklets of the tænia echinococcus were seen, the walls of the large cysts showing laminated structure with considerable leucocytic infiltration. The lumbar and cervical regions of the cord were stained by the Weigert-Pal method and showed well-marked degeneration in the posterior columns, both postero-median and postero-externa being affected in the former, the postero-median alone being affected in the cervical region.

I am indebted to Mr. W. Bevan-Lewis, medical superintendent and director of the West Riding Asylum, for permission to publish this case, and to Dr. T. Dawson, assistant medical officer, for the clinical notes.

Wakefield.

A CASE OF COMPLETE ANÆSTHESIA INVOLVING A SINGLE DIGIT.

BY J. M. POSTLETHWAITE, B.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
AND
JEFFREY RAMSAY, M.B., B.S. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEONS, BLACKBURN AND EAST LANCASHIRE INFIRMARY

THE patient, a painter, aged 22 years, came to the Blackburn and East Lancashire Infirmary in July, 1908, owing to loss of sensation in the middle finger of his right hand. He had noticed nothing abnormal about his finger until he reached the age of 16 years, and so far as he could remember there had never been any injury to his hand or arm. When he was 16 years old he grazed the right middle finger when at work, and he was surprised to find that he felt no pain. Previous to the patient's discovery of loss of sensation in his finger he had been a painter for two years. He had no illness in his childhood with the exception of otorrhea, and his father stated that to the best of his knowledge the patient had no injury of any description when a child. At the age of 17 he had an attack of pneumonia, but as this was after the onset of the digital anæsthesia it can have no bearing on the condition. The patient had never been abroad. His father, mother, five brothers, and one sister were alive and well. One brother died as the result of an accident.

When the patient came
looking man, well-develo
points were noted. His
accommodation; there was no nystagmus and the disc was normal. The tongue was clean and the teeth were fairly good. The throat was normal and there were no enlarged cervical glands. Nothing abnormal could be discovered in the heart, lungs, or abdomen. The skin was dry, but sensation was everywhere normal, with the exception of the finger under consideration. The knee-jerks were brisk and the plantar response was flexor. The urine was acid, of specific gravity 1020, and contained no sugar or albumin.

On inspection the affected finger seemed perfectly normal, with the exception of a partially healed blister on the palmar surface of the distal phalanx, caused by the application of a lighted match to demonstrate the anæsthesia to a group of the patient's friends. Movement was natural. The surface temperature of this finger differed in no way from the rest. Tactile and thermal sensations were entirely lost, and the patient was insensible to pain. (As we stated above, he did not experience any discomfort when a lighted match was held to the finger.) He did not feel a strong galvanic or faradic current when applied to his finger. In order to ascertain if the bones or joints of the finger were in any way affected we obtained an x-ray photograph, which showed no abnormality present. The anæsthesia was very definitely limited to the right middle finger.

The following explanations suggest themselves:—

1. *Syringomyelia.*—Sensations of pain, heat, and cold are lost, which would be in favour of this condition, but tactile sensation is also lost, and in addition to this the main nerve trunks (median and radial) are unaffected, the anæsthesia being limited to the terminal portions of those nerves supplying the middle finger of the right hand. Déjerine states that in rare cases of syringomyelia there may be complete anæsthesia of the skin, and this may possibly be such a case, though there are no other symptoms—for example, irregular pains or muscular wasting—which would point to this condition.

2. A localised peripheral neuritis due to—

(*a*) *Traumatism.*—It is possible that the nerve trunks around the root of the finger may have been crushed during the patient's childhood and have never regained their functions. Such crushing must have been limited to the one knuckle, since sensation is perfect over the whole of the flexor and extensor surfaces of the rest of the hand and of the forearm, and the electrical reactions of all the muscles are normal. The skiagram shows that there is no gross lesion which might be interfering with the digital nerves at *the present time.*

(*b*) *Lead.*—In favour of a lead neuritis is the fact that the patient had been a painter for two years before he noticed the condition. But this explanation is practically put out of court by the fact that there has never been any trace of muscular paralysis. The occurrence of otorrhœa during the patient's childhood suggests the very remote possibility of
ocalised neuritis, but
grounds to the lead
likely that a lead or
diphtheritic neuritis would persist for six years as such a definitely localised condition.

(*c*) *Gummatous affection.*—There were no symptoms pointing to the presence of the disease, and it would be rare indeed for the toxin to affect definitely localised terminations of two separate nerve trunks.

A NOTE ON OPERATION FOR HERNIA AT THE EXTREMES OF LIFE.

By H. W. WEBBER, M.S. LOND.,

SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

CASE 1.—On June 8th, 1908, I was asked by Mr. J. Elliot Square to see a man, aged 93 years, who was suffering from a strangulated inguinal hernia. The hernia was of some years' standing and had been more or less controlled by a truss, but on the present occasion reduction failed to be effected. The old man was in very good general condition and had vomited only twice. A drachm of novocaine solution having been injected subcutaneously over the site of the incision the division of the skin and superficial tissues was effected painlessly, but as much pain was complained of on incising the deeper parts and the patient began to throw himself about chloroform was administered to the stage of light anæsthesia. The hernia was a direct external one and the sac contained six inches of ileum. Reduction of the intestine and closure of the wound were performed in the usual manner, the sac being simply closed with catgut sutures at the neck and left *in situ*. The patient recovered well from the operation and the wound healed with only a little superficial infection. About a month later, however, he developed a cough and was found one morning dead in bed.

CASE 2.—A newly-born male child was admitted to the South Devon and East Cornwall Hospital at 5 P.M. on July 17th, 1908, having been born at 3 P.M. Through the unclosed umbilical opening there projected into the substance of the funis four or five coils of small intestine to a distance of three inches from the level of the skin, forming a pear-shaped tumour, the intestine being very thinly covered with the thinned-out gelatinous matter of the cord. Beyond the tumour the cord was of normal appearance and had been ligatured in the usual manner. The child presented a supernumerary auricle on each side, a cleft palate, and had a supernumerary digit on each hand. At 6.15 P.M. A.C.E. mixture was administered and an incision was carefully made through the thin covering of the intestines which were easily reduced into the abdominal cavity. One of the coils was found to be connected with the tissue of the cord by a thin fibro-gelatinous band which evidently represented Meckel's diverticulum. This was tied with fine catgut and divided. The umbilical opening was then closed with three catgut sutures and the edges of the skin approximated. The child took very little nourishment, became gradually weaker, and died early on July 19th.

Plymouth.

Medical Societies.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held on March 30th, Dr. T. S. Kirk, the President, being in the chair.—The following specimens were shown:—Professor T. H. Milroy and Dr. J. A. Milroy showed Microscopical Preparations of the Nervous System.—Professor T. Sinclair showed a series of large Vesical Calculi, a series of Gall-stones, a Cystic Kidney, a Pancreatic Cyst, Cancer of the Sigmoid, and Cancer of the Rectum.—Dr. Howard Stevenson showed a specimen of Tuberculosis of a Horse-shoe Kidney.—Dr. J. W. Browne showed a Duct Cancer of the Breast.—Sir John Byers showed an Ovarian Tumour removed during Pregnancy, an Ovarian Tumour removed from a patient aged 80 years, a Tubal Abortion, and several other gynæcological specimens.—Sir John Byers and Dr. W. J. Wilson showed a Syphilitic Fœtus with well-marked Wegner's osteochondritis occurring at the epiphyseal borders of the hollow bones. The woman who gave birth to the fœtus at the maternity was covered with rupia spots.—Dr. G. A. Hicks showed three Uteri removed for uncontrollable hæmorrhage with polypoid endometritis, submucous myoma of the fundus, and carcinoma of the fundus.—Dr. H. Hanna showed an Intraocular Tumour, Cancer of the Larynx, and a Lacerated Eyeball with a large foreign body.—Mr. A. Fullerton showed a Gall-bladder with stones *in situ*.—Mr. R. J. Johnstone showed a large Myoma (undergoing submucous degeneration) springing from the cervix.—Mr. Robert Campbell showed an enormously thickened Parietal Pleura excised, a Gall-bladder with a Stone blocking the Cystic Duct, and a Gall-bladder completely filled by Stones.—

He described a series of experiments in which a second dose of horse serum produced an alarming effect (high fever, œdema, and rashes) in guinea-pigs and even death in some cases, and also described cases of Scarlet Fever in which similar but less severe symptoms had followed a second dose of serum.—Dr. Wilson read a short paper on an Original Method of Isolating the Typhoid Bacillus most useful in the case of water. He also read a communication on the Investigation of the Blood in Typhus Fever, and showed that in 11 out of 17 cases examined Widal's reaction was present, so that culture experiments were necessary to make a diagnosis between typhus and enteric in reference to the organism in the blood.—Dr. T. Houston made a communication on the Further After-history of a Typhoid Carrier.—Dr. J. S. Dickey read a short paper on the Surface Relations of the Apex of the Lung, in which he showed that a careful examination of a series of cadavers demonstrated that the cervical portion of the lung was within the inner fourth of the clavicle.

LIVERPOOL MEDICAL INSTITUTION.—The last pathological meeting of the session of this society was held on April 1st, Mr. T. H. Bickerton, the President, being in the chair.—Dr. O. T. Williams showed Tubercle Bacilli from Cerebro-spinal Fluid.—Dr. R. W. McKenna exhibited specimens of Spirochæta Pallida.—Dr. E. E. Glynn showed: (1) A Gummatous Heart; and (2) a Cerebellar Cyst.—Dr. R. E. Harcourt and Dr. E. Stevenson exhibited: (1) Sarcoma of the Eye Growing from the Disc; and (2) Sarcoma of the Orbit.—Dr. J. Lloyd Roberts showed an Aneurysm of the Arch and Descending Part of the Thoracic Aorta.—Dr. A. Nimmo Walker read a note on the Application of Bacteriology to Eye Surgery. He described the methods of bacterial examination of the conjunctival sac in: (1) cases of purulent discharge; and (2) clean cases previous to operation. At St. Paul's Hospital this examination was the routine practice and he strongly emphasised the value and necessity of such. He illustrated his remarks by cases, films, and cultures.—Dr. Glynn read a note on Hepatic Cirrhosis with Adenomata and Carcinoma. A male, aged 49 years, died after eight months' illness. He had all the signs of cirrhosis, slight jaundice, and latterly the liver was enlarging. Post mortem the liver weighed 119 ounces and showed (1) multilobular cirrhosis of the right lobe, with circumscribed green "adenomata," and microscopically many bile-containing tubules, also diffuse white growths, resembling spheroidal-celled cancer, infiltrating the portal vein and causing [illegible]larged spleen; (2) there was marked compensatory hyper[illegible]phy of the left lobe, with a few "adenomata." There [illegible]re no growths in other organs.—Dr. J. Hill Abram and Dr. [illegible]. G. Gullan discussed the note, referring to three or four similar cases which they had met with. One of Dr. Abram's cases was associated with secondary growths in the anterior mediastinum.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 2nd, Dr. Leslie Durno, Vice-President, being in the chair.—Mr. J. Houston Porter showed two cases of Achondroplasia, the patients being brothers, aged 50 and 52 years respectively. They presented many of the characteristic features of achondroplasia—namely, marked micromelia, the shortness of the limbs affecting the upper segments more than the lower, as is usually the case, the upper arm and thigh being shorter in proportion than the forearm and leg. The affected long bones showed considerable exaggeration of the normal curves, this being well exemplified in radii and femora. The epiphyses were in nearly every case thickened and nodular, the result of excessive and irregular deposition of subperiosteal bone. The feet were small, owing to the shortness of metatarsals and phalanges, and square in shape. The gait was decidedly rolling and waddling. The skull was of the usual type found in these subjects. The bones of the vault, which were developed in membrane, were of at least average size and usual shape, while those of the base, which were developed in cartilage and underwent an early synostosis, were small. The face was thus in general outline triangular, the small lower jaw producing a pointed chin which formed the apex of the inverted triangle. Their father, grandfather, uncle, and another brother were similarly affected.—Mr. P. Maynard Heath showed a woman, aged 33 years, who six months ago had been operated on for chronic abscess of the left breast. Four months ago she developed a chronic induration of the skin of both breasts and upper arms which was thought to be probably myxœdematous.—Mr. Heath also showed a woman, aged 46 years, with fatty enlargement around the left elbow.—Dr. T. Galbraith read notes of a case of Atheroma of the Left Coronary Artery with fatal Angina Pectoris in a woman, aged 45 years.—Dr. L. U. Young related a case of Labour complicated by Uterine Fibroid in a primipara, aged 42 years. He also described a case of Puerperal Eclampsia in a primipara, aged 24 years, which he had successfully treated by saline transfusions, chloroform inhalations, and morphine injections.

Reviews and Notices of Books.

Guide to the Clinical Examination and Treatment of Sick Children. By JOHN THOMSON, M.D. Edin., F.R.C.P. Edin.; Physician to the Edinburgh Hospital for Sick Children; Joint Clinical Lecturer on Diseases of Children, University of Edinburgh; Honorary Member of the American Pediatric Society. Second edition, greatly enlarged and rewritten. With 160 illustrations. London and Edinburgh: William Green and Sons. 1908. Pp. 629. Price 12*s.* 6*d.* net.

IT is a pleasure to review so thoroughly practical a work on the clinical aspects of disease in children as that written by Dr. John Thomson. It is the second edition of a book published ten years ago, but it has been more than doubled in size, although retaining the general character of the original edition. The most admirable feature is the clear and concise manner in which the special characteristics of disease in childhood are presented. The author obviously draws his descriptions from his own experience, while recognising and paying due attention to the work of others. The book is liberally illustrated, for the most part by reproductions of photographs of cases observed by the author himself, which serves to accentuate the personal note in the character of the book. The arrangement of the subject matter is also to be commended. The various diseases are not described according to any stereotyped plan, and the separate chapters are devoted to a consideration of the clinical phenomena to be observed in regard to a given system, or to a study of a special symptom, or of groups of symptoms, and of their significance in diagnosis. This method of treating the subject renders it more interesting and more instructive than a mere categorical enumeration of symptoms and physical signs.

The first chapter includes some useful hints on the manner of carrying out the routine examination of infants and children, and also some instructive examples and illustrations of the physiognomy of disease in these periods of life. [A useful chapter on dentition contains a well-balanced discussion of the part played by that process as a factor in the causation of disease. Dr. Thomson rightly considers that the wisest position to adopt is that of avoiding the extremes of opinion, according to which dentition is regarded, on the one hand, as the cause of a multitude of ills, or, on the other, as a purely physiological process never accompanied by unpleasant symptoms. Another subject which is dealt with in a critical and interesting manner is that of hypertrophic stenosis of the pylorus, or congenital spastic hypertrophy of the pylorus, as Dr. Thomson prefers to call it. This is a subject to which he has devoted special attention, and as he has personally observed 41 cases it is one on which he is entitled to write with authority. He gives the views of other observers and also that which he has put forward—viz., that the hypertrophy of the pyloric musculature is the result of overwork due to defective coördination. He also discusses at some length the treatment, both surgical and medical. The "mucous disease" of Dr. Eustace Smith is described under the name of chronic intestinal indigestion, and Dr.

Thomson gives detailed instructions for the dieting and treatment of this somewhat indefinite condition. He deprecates the common practice of giving cod-liver oil, ferruginous tonics, and excess of farinaceous foods to children suffering from this condition on the supposition that they are suffering from "debility." We may mention as specially interesting the chapters on jaundice, on some diseases of the blood and blood-forming organs, on mental defect, and that on rickets and certain other diseases affecting the bones. In the chapter on certain respiratory diseases the accounts given of the physical signs and symptoms are less complete than might be expected, notably in regard to empyema. In the preface Dr. Thomson states that he has not confined his attention entirely to common ailments, but has been guided in the choice of subjects by his own experience and predilections. Some of the most interesting and instructive parts of the book are those dealing with more or less uncommon malformations or diseases; among these we may mention "congenital unilateral pectoral defects" and Hirschsprung's disease. The important practical questions of infant feeding, nursery hygiene, and general therapeutics each have a special chapter devoted to them, and in these will be found many valuable hints the outcome of personal experience.

The scope of the book is avowedly clinical and therefore pathological questions are either omitted or very briefly noticed. The leading characteristic which makes this book so praiseworthy is the sound common sense which illuminates it throughout, and we can cordially recommend it to our readers as both interesting and helpful.

[illegible] Forty- [illegible]., 1908.

THE annual volume of the transactions of the American Ophthalmological Society always contains interesting and instructive matter. In the present one Dr. de Schweinitz and Dr. Holloway contribute an excellent paper on Five Cases of Sudden Obstruction of the Central Artery of the Retina, a condition usually less accurately described as embolism. Particularly noteworthy in these cases are the occurrence of central or paracentral scotomata and the preservation of some vision in the temporal part of the field. As regards the latter, in the particular case where it is described it appears to have been more central than in most of the other cases recorded elsewhere. An allied condition, embolism of a macular artery and thrombosis of superior and inferior retinal arteries in a case of embolic softening of the brain, is commented upon by Dr. Shoemaker. In this case a pathological examination of the eye was possible. Dr. Quackenboss and Dr. Verhoeff report a rare case of angioma of the orbit invading the globe along the ciliary nerves. Dr. Kipp adds cases of macular holes to the now considerable number already on record. Polycythæmia has recently attracted attention in medical circles. Dr. Tyson has added to the scanty [illegible] of a cas [illegible] tubercu [illegible] cutaneous reaction of von Pirquet are worthy of special attention at the present time; they have led him to conclude that phlyctenular conjunctivitis is tuberculous. Interstitial keratitis in acquired syphilis is by no means so rare as has been thought; the subject is discussed in all its bearings by Dr. John T. Carpenter. Major Henry Smith, I.M.S., contributes a paper on his now well-known method of extracting immature cataract in its capsule; the discussion which ensued is a familiar example of the difference of opinion which exists on the matter. Space does not permit of further reference to many other communications of interest. The volume is fully up to the average and m all ophthalmologists. Of still wider soci ance is the report of the committee neonatorum, presided over by Dr. Lucien Ho

---

Archives of the Middlesex Hospital. Vol. XIII. The Seventh Report from the Cancer Research Laboratories. Edited for the Cancer Investigation Committee by W. S. LAZARUS-BARLOW, M.D. Cantab., F.R.C.P. Lond. London: Macmillan and Co. 1908. Pp. 208.

THIS volume opens with tabulated synopses of the post-mortem examinations and operations in cases of malignant disease in the Middlesex Hospital during the year 1907. In all 222 cases (males 64, females 158) were examined microscopically. Particulars are given of the nature of the new growth, the sites of secondary growth, and other morbid changes found in all fatal cases.

Dr. Victor Bonney describes a new and rapid triple stain, a modification of a process published by him in THE LANCET of Jan. 27th, 1906. The stains employed are methyl violet, pyronin, and orange-G. The same author contributes an important paper on the Connective Tissue in Carcinoma and in Certain Inflammatory States that Precede its Onset, which formed the subject of his Hunterian lectures.[1] Dr. Archibald Leitch records his observations on secondary malignant conversion of epithelium, as a result of which he concludes that "a carcinoma having once started from a definite focus can be added to by conversion of previously non-malignant epithelium *of the same kind* (1) in direct continuity with, (2) in immediate proximity to, and (3) within the sphere of influence of, the growing edge." Dr. L. Courtauld and Dr. A. Leitch describe the occurrence of lumina in malignant tumours and regard them as capable of separation into three groups: first, those formed by cell necrosis; secondly, those formed by irregular cell proliferation; and thirdly, those representing pre-existing channels. Dr. Hector A. Colwell gives the results of some experiments on the action of thorium and uranium upon certain ferments. The emanations from radium have been shown to exert a destructive effect upon certain digestive ferments, and Dr. Colwell finds that thorium and uranium exert a similar effect. The same observer records a research to ascertain the effects of urinary and biliary calculi upon photographic plates in the dark. He finds that both of them produce definite shadows revealed by development, the effect of gall-stones being greater than that of vesical calculi. The shadow produced by gall-stones is larger than the area of the stone in contact with the plate, which is never the case with vesical calculi. The effect is not due to uric acid, urates, oxalates, phosphates, cholesterin, or pigment as such. Dr. W. S. Lazarus-Barlow describes the results of a similar research with animal tissues. He finds that the greatest photographic effect is produced by liver, brain, and kidney, while spleen and lung produce effects in only a minority of the cases, and then only effects of low values. The photographic value of the liver increases in both sexes from infancy to the age of 55 years; after that age it increases still further in males, but undergoes a great diminution in females. At all ages except those over 55 years the photographic value of the female liver is greater than that of the male. Carcinomatous and sarcomatous material, both primary and secondary, produce effects which are about as strong as that of liver, and the values of female tissues are greater than those of male. Dr. Lazarus-Barlow contributes a second paper, which forms a preliminary communication regarding an experimental inquiry into the nature of this property. It appears not to be due to protein, fat, cells, pigment, or blood as such, nor is it apparently due to the ordinary non-volatile inorganic constituents. It is different from the photographic properties manifested by recognised radio-active substances on the one hand and substances such as wood on the other, although it appears to have affinities with both.

---

[1] THE LANCET, May 16th (p. 1389), 23rd (p 1465), and 30th, 1908 (p 1535), respectively

Mr. Cecil W. Rowntree, in a paper entitled a "Contribution to the Study of X Ray Carcinoma and the Conditions which Precede its Onset," gives brief details of five cases. He states that examination of the specimens showed them to be examples of typical squamous-cell carcinoma. Mr. Rowntree (whose Hunterian lecture on the same subject was published in our issue of March 20th), describes the results of the application of the rays to the human skin and to the tails of rats, and concludes that the application of the x rays to healthy tissues results in the stimulation of normal physiological processes—i.e., the growth of epithelial and other cellular elements; that a single large dose may result in an acute change resembling an ordinary burn or a destructive dermatitis; that administration for a long period ultimately results in complete atrophy of the epithelial elements and degenerative changes in the connective tissues; and that these changes ultimately lead to a state which disposes to the occurrence of carcinoma. Mr. Rowntree also describes a simple and ingenious form of apparatus for drawing from the microscope.

Dr. Lazarus-Barlow is to be congratulated on the good work represented by the researches carried out in his laboratory, all of which have for their object the acquisition of information in regard to the complex problems involved in the incidence and spread of cancer within the body, and although some of the work is highly technical in character and sometimes of little apparent utility it represents necessary pioneer labour in regard to some phase or other of this difficult subject.

Principles of Sewage Treatment. By Professor Dr. DUNBAR, Director of the Hamburg State Hygienic Institute. Translated with the author's sanction by H. T. CALVERT, M.Sc., Ph D., F.I.C. With 147 illustrations. London: Charles Griffin and Co. 1908. Pp. 271. Price 15s. net.

THE disposal of excreta, once an individual consideration, is now a collective one, and the fact that concentrated populations have to be dealt with renders a system necessary which embraces the problem of sewage disposal as a whole. It is not a little interesting to reflect that in spite of the enormous attention directed to the subject by chemists, biologists, engineers, and others, the outcome of their joint labours may indicate as a possible solution of the question a biological process—which in principle amounts to the simple method adopted by the individual before a water carriage system forced itself upon the attention of communities. The disposal of excreta by shallow burial in the earth amounted to the resolution of human filth by biological agencies, and a very satisfactory method it proved so long as the agencies were not overtaxed. With the introduction of the water-carriage system the problem of the disposal of large volumes of water contaminated with fæcal matters had to be faced. This was, and is still, *the* sewage problem. The water-carriage system succeeded well enough in removing human excreta away from the house and pouring it into channels remote from habitable places, and thus far satisfied a policy of "out of sight out of mind." But this meant a discharge of sewage into the rivers and it was soon found that sewage treated in this way was far from being "out of sight out of mind," for there became evident the very unwelcome and unpalatable fact that these rivers were being dangerously polluted, and were rapidly becoming a
menace to the people's water-supplies and to the pı
health in general. The problem of sewage disposal
soon resolved itself into the question of the prevention o
pollution of rivers which at first had been regarded as
venient channels of disposal, channels which could sustai
pollution on account of their self-purifying powers. Ri
no doubt, possess self-purifying powers, but the popula
of their banks have increased to such an extent in n
instances that the river has become a stinking sewer.
short, the introduction on a large scale of the water-c
not so many years ago soon placed a strain on our r
to which they were unequal, and sewage and fac
refuse combined to destroy the beauties of sylvan strean

The interesting story of how this spoliation
been checked, and how far further application
new and improved methods promises to bring back
rivers to their pristine beauty and cleanliness, is well
ably told in Professor Dunbar's work, for the excellent t
lation of which the thanks of all sanitarians are due t
H. T. Calvert, whose experiences as the chief chen
assistant to the West Riding of Yorkshire Rivers Board
specially well qualified him for the task. It is dou
whether the subject in both its historical aspects and i
relations to modern investigation has before rece
such thorough and comprehensive discussion. Pos
ing a sound acquaintance with chemical and bact
logical subjects, Professor Dunbar writes confidently
authoritatively on those problems connected with sev
disposal which involve the application of bacteriolo
and chemical principles. Nor has he confined his atten
merely to the troubles encountered in connexion with
attempted application of these principles to sewage work
his own country, but gives also an interesting and
prehensive account of the experiences of other countries w
a solution of the problem is equally urgent. In partic
we may observe that the last chapter on the utility and
of the various methods of sewage treatment shoul
invaluable to the officers of sanitary corporations who
at heart the needs of their own districts and who
anxious to meet these needs in the most efficient
economical way. We heartily commend the book a
peculiarly fair and impartial statement of the present p
tion of the sewage problem.

Leçons Élémentaires de Microbiologie Générale. Par M. E
POZZI-ESCOT, Professeur de Chimie et de Microbiolog
l'École Nationale d'Agriculture et de Médecine Vétérin
de Pérou; Laureat, Medaille d'Or de l'Association
Chimistes de Distillerie de France et des Colon
Paris: Jules Rousset. 1909. Pp. 366. Price 9 franc

THE author of this work considers, and we think righ
considers, that the science of microbiology is one in
principles and in its general laws, quite irrespective
the many various fields of study into which, in
practical applications, it may extend. Professor Poz
Escot holds, therefore, that a general course of bacter
logy, in which the fundamental principles of the scien
are developed, should be equally suitable for the educ
tion of the physician, the veterinary surgeon, or t
agriculturist. The present book embodies these views, a
consequently, though it is founded upon lectures delivered
the National School of Agriculture and Veterinary Medici
of Peru, yet it is only in the choice of certain illustrati
examples of the practical applications of the theoretic
principles taught that the special nature of the course
shown or that there is any exact adaptation to the needs o
the veterinary or agricultural student. This book therefor
differs widely from the usual manuals of bacteriolog
intended for the medical student, as may be seen by the

fact that the special descriptions of the pathogenic microorganisms, which usually constitute the bulk of such works, are disposed of in some four or five pages. The subject is viewed from the standpoint of the chemist and not from that of the pathologist, and the influence of the late Professor Duclaux seems to have strongly affected the style and method of treatment of the subject. The author explains everything, including the life of the cell itself, on purely chemical grounds, or at any rate as the result of purely chemical and physical forces, and this conception tinges the teaching of the whole book. Pathogenic action is regarded as a function of toxin production, and no essential difference is recognised, so far as pathogenesis is concerned, between those organisms which produce extracellular and those which produce intracellular toxins. A glance over the table of contents, which, unfortunately, as in so many French works, is made to take the place of an index, does not show the essential difference between the book and others of the more usual type the regular chapters on the biology and physiology of microbes, on microscopic and cultural technique, on diastases, toxins, antibodies, on theories of immunity, are to be found, but these subjects are all treated on the principle enunciated above. The chemical views of Ehrlich are naturally welcome, but the French influence prevents any neglect of the cellular theories of immunity.

In the later part of the book (Chapter IX. *et seq.*) a more detailed account of industrial, and especially alcoholic, fermentation is given, and finally a short account of the chemical changes produced by organisms in the soil. The book is illustrated by woodcuts, many of which seem to be reproductions of rough pen drawings which contrast with the usual process reproduction of photographs. The subject is treated with the clearness of thought and style which we are accustomed to associate with French literature. The paper, type, and binding are creditable to the publisher.

LIBRARY TABLE.

Dreschfeld Memorial Volume, containing an Account of the Life, Work, and Writings of the late Julius Dreschfeld, M.D., F.R.C.P., with a Series of Original Articles Dedicated to his Memory by Colleagues in the University of Manchester and Former Pupils. Edited by E. M. BROCKBANK, M.D. Vict., F.R.C.P. Lond. Manchester: at the University Press. 1908. Pp. 246. Price 10*s.* 6*d.* net.—The custom of honouring men of mark by the publication of volumes of scientific papers dedicated to them, whether it be on the occasion of some anniversary in their lives or as a posthumous tribute of respect, is one which has much to commend it. The volume before us worthily carries out the principle involved, containing, as it does, much valuable work which if it do not ultimately prove "ære perennius" is yet well calculated to do honour to a lamented teacher. The contents of the book have already appeared in the Memorial Numbers of the *Medical Chronicle* and have been noticed in our columns; they need not, therefore, be here enumerated. The preliminary memoir gives a good account of the late Professor Dreschfeld and is followed by a list of his medical writings amounting to over 100 in all. In him Manchester has lost a skilled physician, a diligent worker in the field of medical science, and a valuable teacher.

Compte Rendu des Travaux du Ier Congrès International de Psychiatrie, de Neurologie, de Psychologie et de l'Assistance des Aliénés, tenu à Amsterdam du 2 à 7 Septembre, 1907. Rédigé par le Dr. A. M. VAN WAYENBURG, Secrétaire Général du Congrès. Amsterdam: J. H. de Bussy. Pp. 934.—The proceedings of this Congress are divided into three parts. The first section is concerned with Psychiatry and Neurology, the second with Psychology and Psychophysics, and the third with the Care of the Insane. The id national congress of this character appears to mooted at the Netherlands Society of P *Neurology and to have been the offspring of an op* such a congress would be in the interest of the development of our knowledge of the life of the nervous system of man in all its manifestations. It was hoped that it might lead to an exchange of views and opinions at greater length and with greater facility than is possible in the more narrow limits of a section of a general medical congress. The proceedings before us afford ample testimony that the hopes of those who initiated the Congress have had a satisfactory fulfilment. The value of the several communications necessarily varies but a high standard has throughout been maintained, and we would mention as of special interest Professor van Gehuchten's paper upon Le Mécanisme des Mouvements Réflexes; Professor Dupré's paper upon the Diagnose Différentielle entre la Démence Paralytique et les autres Formes de Démence Acquise; Dr. M. M. A. Marie and Dr. *Viollet's Argument en faveur de l'Origine Syphilitique de la* Paralysie Générale; the papers contributed by Professor Arnold Pick, Professor von Monakow, Professor Liepmann, and Professor Hartmann upon Asymbolie, Apraxie, Aphasie; and lastly, the paper of Dr. A. Marro upon the Psychologie de la Puberté. We congratulate Dr. van Wayenburg upon the successful issue of his secretarial duties.

Medical Reports of the Central London Throat and Ear Hospital. Vol. I. London: Adlard and Son. Pp. 134. 1908. Price 5*s.*—This volume contains the following articles: the Retention of the Matrix in Operations for Cholesteatoma of the Middle-ear, and Cases Illustrating the Operative Treatment of Septic Lateral Sinus Phlebitis without Ligature of the Jugular Vein, by Dr. J. Dundas Grant; Remarks on Mastoid Operations, by Dr. Percy S. Jakins; the Operative Treatment of Nasal Sinus Suppuration, by Mr. W. J. Chichele Nourse; Clinical Cases, by Dr. P. H. Abercrombie; Cranial Complications of Otitic Origin, by Mr. W. Stuart-Low; Notes on Cases of Malignant Disease of Pharynx and Larynx, by Dr. A. Wylie; Brief Notes of Cases of Interest, by Dr. J. Atkinson; Adenoids, &c., by Dr. D. McKenzie; a Review of 30,000 Administrations of Anæsthetics for Operations on Throat and Nose, by Dr. A. B. Kingsford; and Pathological Reports, by Dr. V. H. W. Wingrave. From the above list it is evident that there is no tabular statement of cases seen during the 30 odd years which have elapsed since the opening of this hospital and the issue of Volume I. of the Reports. These may possibly be issued in a future number.

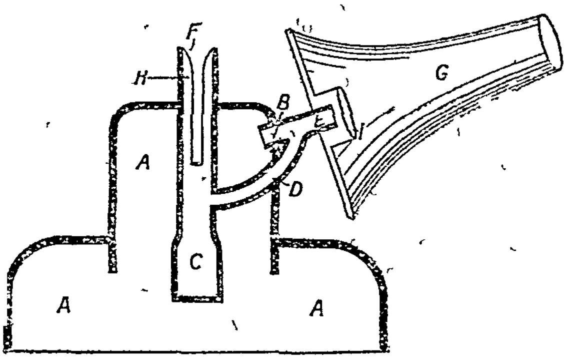
JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXVIII., No. 4, March 22nd, 1909. London: Cambridge University Press Warehouse. Price 6*s.* 6*d.*—The contents of this number are as follows: 1. The Transformations in the Phosphorus Compounds in the Hen's Egg during Development, by R. H. Aders Plimmer and F. H. Scott. 2. The Optical Properties of the Contractile Elements in Heliozoa, by Doris L. Mackinnon, B.Sc., Carnegie Scholar (1907-08). 3. Further Note on Adrenalin Isomers, by Arthur R. Cushny, from the pharmacological laboratory, University College, London. 4. The Natural Channels of Absorption evoking the Chemical Mechanism of Gastric Secretion, by J. S. Edkins and M. Tweedy, from the physiological laboratories of Bedford College and St. Bartholomew's Hospital. 5. Axon Bifurcation in Regenerated Nerves, Part II., by W. A. Osborne and Basil Kilvington, from the physiological laboratory, University of Melbourne. 6. Fatty Infiltration of the Liver in unger, by V. H. Mottram, Fellow of Trinity College, Cambridge, Plates 2 and 3, from the physiological laboratories of ambridge and Munich. 7. The Mode of Action of Specific ubstances, with Special Reference to Secretin, by W. E. ixon and P. H. A. Mill, from the pharmacological laboratory, Cambridge. 8. The Pressor Principles of Placental Extracts, by Otto Rosenheim, from the physiological laboratory, King's College, London. 9. Isolation of the Pressor rinciples of *Putrid Meat*, by G. Barger and G. S. Walpole, rom the Wellcome physiological laboratories, London. This number contains also the Proceedings of the Physiological ociety for Feb. 27th, 1909.

New Inventions.

AN IMPROVED INHALATION AND DISINFECTION APPARATUS.

THIS invention is designed to afford an improved apparatus for impregnating air with drugs and for inhalation purposes. The ordinary spray apparatus, such as the nebuliser, do not effectively answer their purpose, because the substances used in them, however minutely divided, are yet, taken in the aggregate, necessarily delivered in the form of drops of liquid so used. Again, the drug used does not reach the whole of the lung substance, a great deal of it settling in the bronchi and upper portions of the lung. This apparatus, which is shown in section in the figure, consists of a boiler, A, having a nozzle outlet, B, and a receptacle, C, in which the substance is volatilised and which is contained within the boiler but does not directly communicate with it. This receptacle has an air inlet and a nozzle outlet, D, located in apposition with the boiler outlet in such a manner that the steam issuing from the latter sucks up the vapour of the substance under volatilisation contained in the receptacle and carries it off with it. The two outlet pipes join at their distal extremities into a short broader tube and consequently end in one common nozzle, E. The steam pipe, which is uppermost, is short and straight, whilst the lower vapour pipe is broader, longer, and curved. The vapour arising from the drugs in the receptacle is assisted in its exit (1) mainly by the pressure of the current of fresh air entering through the funnel-shaped opening in the cap, F, of the tube, so that the drug vapour is kept constantly escaping and is being as rapidly replaced by fresh air; (2) also to some extent by the suction-like action exerted by the steam as it issues from the boiler tube and passes over the point of exit of the vapour tube; and (3) to some extent by the pressure of the vapour itself. The steam becomes saturated with the vapour of the drug or drugs used and is distributed through the glass trumpet G, the smaller end of the trumpet being employed for inhalation and the larger end for disinfecting purposes or for impregnating the air of the room. The said trumpet is supported upon a perforated circular platform, which is fixed in position by means of a wire loop surrounding the upper extremity of the tube H and carries four clips and a central raised ring so arranged as to support the trumpet in either [illegible] amount of water required for the boiler [illegible] measure which accompanies the appara[illegible] is also a small spoon for the drug. Except for the glass funnel, the whole apparatus, which is six inches in height, is made in white polished metal. The boiler stands upon a tripod, beneath which is a small metal spirit lamp. These are not shown in the figure.



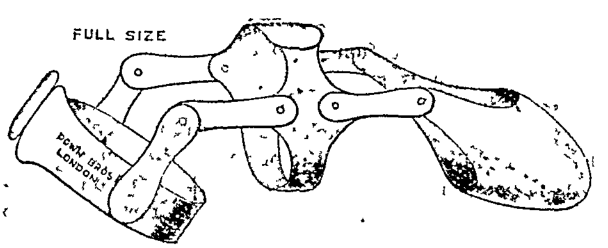
The advantages claimed for this apparatus may be briefly summed up as follows. 1. It is compact, light, and very simple to operate. 2 The steam and vapour are both driven through a common nozzle instead of through two separate nozzles, thereby making the intermixing absolute and insuring a more concentrated vapour. 3. Disinfectants used in a vaporous condition have a much more beneficial effect than when used in [illegible] and the apparatus fully vaporises the d[illegible] 4. The drug or drugs used are quite [illegible] our or the water in the boiler. 5. The consumption of the drug is very economical. 6. The drugs used may be in the solid, liquid, or crystalline form. 7. The vapour arising from the drug or drugs is so intimately intermixed with the steam that when inhaled it perfectly penetrates every portion of the lung. By the use of this apparatus the vapour, whether inhaled directly from the tube or indirectly through the air of the room, will reach every part of the lung, even the pulmonary alveoli. 8. The apparatus may be set working in a room a quarter of an hour or so previously to a patient going to bed, so that the patient will be breathing an atmosphere saturated with the drug; this is most useful and beneficial in cases of pulmonary tuberculosis, asthma, and chronic bronchitis.

The apparatus will be found useful in the treatment of rhinitis, pharyngitis, tonsillitis, laryngitis, asthma, emphysema, phthisis, hay fever, gangrene of the lung, whooping-cough, and other respiratory diseases The following are examples of substances that can be used for evaporisation or volatilisation in the receptacle: menthol, eucalyptus, carbolic acid, lysol, thymol, mercury, creosote, terebene, stramonium, lobelia, or any combination of these drugs.

A. G. WHITEHORNE-COLE, M.R C S., L.R.C.P.
Brighton.

METAL FINGER-GUARD FOR USE AS DIRECTOR.

SOMETIMES during surgical operations it is very convenient to cut down upon the finger as a guide. When, for instance, in a septic peritonitis following perforated gastric ulcer it is desirable to drain the loins or pelvis the most convenient way of making a counter opening is to cut down from without upon the forefinger inserted in the original wound, because the finger can feel whether anything is in the way or not. If an instrument is inserted for this purpose it may easily involve a piece of intestine in the counter-opening. But if the gloved finger be used unguarded counter puncture has to be made carefully and deliberately lest the glove and, more serious still, the finger of the surgeon beneath it be cut. Again, a large abscess may be pointing and be opened in front of the thigh It is desired after opening it to make counter punctures for better drainage at the sides. The finger is again the most convenient guide, because it can feel exactly the most dependent point of the abscess cavity. Examples could easily be multiplied and will occur to every surgeon. To protect the finger when thus used as a director I have had the finger guard, as depicted in the accompanying illustration, made for me by Messrs Down Bros., and have found it very useful. It allows of as free flexion of the finger as if the latter were unguarded and it can be cut down upon straight away. When used inside the abdomen the forefinger, encased in the finger guard, and the middle finger are inserted together. The latter feels that nothing is in the way, and the guarded forefinger is then cut down upon at once with a single stroke of the knife. The instrument should be made to fit the finger of the surgeon using it.



CHARLES P. CHILDE, B.A., F.R.C.S. ENG.,
Senior Surgeon, Royal Portsmouth Hospital.

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1909.

An Imperial Bureau of Anthropology.

MOST of our readers, and especially anyone who has observed the success which has attended the foundation of schools of tropical medicine in this country, will appreciate the efforts now being made by leading British anthropologists to establish an Imperial Bureau of Anthropology. Schools of tropical medicine confer a double benefit; they not only fit medical men to begin work at once in a new sphere of disease, but they have also been the direct means of a rapid advance and wide diffusion of useful knowledge and fresh discovery. By the foundation of an Imperial Bureau of Anthropology it is hoped that those who enter the Indian, Colonial, Egyptian, or Consular services, whether in political or medical capacity, may have opportunities of preparing themselves for their new conditions of life and work similar to those at present enjoyed by medical men proceeding on tropical service. At such a bureau the newly appointed medical officer, even if delegated to a remote tribe or people, would find, as would the political cadet, all that is known of the language, laws, religion, customs, commerce, physical characters, and diseases of the population whose affairs have to be administered, and would also receive instruction as to the best means of increasing by further observation the available stock of knowledge. Never before in any period of the world's history has a nation possessed our present opportunities of gathering up and systematising the tangle of facts and guesses relating to the physique, the lives, and the habits of primitive races. That is the task which the founders of the Imperial Bureau have set before them, but so far they have failed to obtain official recognition.

A few weeks ago a deputation consisting of Professor WILLIAM RIDGEWAY, professor of archæology in the University of Cambridge and President of the Royal Anthropological Institute of Great Britain and Ireland; Sir RICHARD TEMPLE, who has been, like his famous father and namesake, a highly distinguished Indian official and who is also an authority on Indian ethnology; Sir EDWARD T. CANDY, late a judge of the Indian High Court; Sir HARRY JOHNSTON, of Uganda fame and a trustee of the Hunterian Museum; Mr. S. H. BUTCHER, M.P.; Mr. HART DAVIES, M.P., and other men of high standing, waited on the PRIME MINISTER and presented a memorial urging the Government to establish such a bureau. All they asked for by way of a commencement was official recognition and the modest annual subsidy of £500, the Royal Anthropological Institute offering to supply the necessary accommodation and library. The PRIME MINISTER's reply was unfavourable, and also, in our opinion, not wholly just. While admitting "that anthropology was not only an important but an indispensable branch of knowledge, not merely for scholars but for persons who were going to undertake in an Empire like ours—whether in India or the Crown colonies—the work of administration," he held out no hope of financial support because "there were 50 or 100—certainly 50—institutions and societies all carrying on most excellent work and founded on a voluntary basis, and all of which could contend with great plausibility that their efficiency and comfort and convenience would be greatly increased if an annual subvention were granted to them." For the excellent service it offered to undertake the deputation was turned away not only empty-handed but with the suggestion that it had sought help under false pretences. It is not necessary to guess what would have happened to such a deputation in Germany or France: its beneficent objects would have been perceived, and sympathy certainly, and probably a subsidy would have been offered at once. Too often the methods of foreign governments are cited as the standard which our statesmen should copy, and those who protest in their patriotism that they are a little tired of such futile comparisons are often justified. But in scientific affairs, as in education of a technical character, our insular way, which has always been to depend on voluntary effort, implies, we think, too great a reliance on the generosity and sagacity of a few. The Imperial Bureau of Anthropology will succeed in all probability through the work of enthusiastic individuals, and the government of the country will reap all the benefit without taking any of the responsibility. We are glad to learn from private sources of information that officials who stand high in the Indian and Colonial administrations are warm advocates of the scheme and are likely to afford it official and financial support. Germany, we believe, spends about £10,000 a year in having the work done which the Imperial bureau has vainly offered to do for exactly 5 per cent. of that sum. It is, however, to the much and perhaps in some respects justly abused Belgium administration of the Congo Free State that we must turn to see an Imperial Bureau of Anthropology really at work. The Belgian Minister of Education is its official head. At the present time it is issuing a series of ethnological monographs on the various tribes which inhabit that vast state. The monograph on the Basongo tribe, issued in 1908, runs into 557 pages. It commences with a general introduction to the present-day knowledge of the tribe and of the Europeans who discovered and described them; then follows a complete list of the literature dealing with the tribe; all that is known concerning the geography of their country, of their psychology, physique, dress, food, houses, villages, occupation (hunting, fishing, agriculture, pottery, carving), religion, fetichism, language, amusements, society, laws, government, marriage, and diseases. The knowledge thus codified is not only of great service to those whose special study is primitive man but of even greater value to the young official when he first sets foot on tropical soil. In support of this fact we cannot do better than quote Professor RIDGEWAY's words when introducing the deputation whose objects failed to appeal to the PRIME MINISTER.

"Several of our most distinguished Indian and Colonial administrators have pointed out that most of the mistakes made by British officials are due to their ignorance of the habits and customs of the natives. It has been in the past an axiom of British politicians that in the English constitution and in English law there is a panacea for every political and social difficulty in any race under the sun. The fundamental error in this doctrine is the assumption that a political and legal system evolved during many centuries amongst a people of North-western Europe largely Teutonic, and that, too, living, not on the mainland, but on an island, can be applied cut and dried to a people evolved during countless generations in tropical or subtropical regions with social institutions and religious ideas widely different from those of even South Europeans and still more so from those of Northern Europe. We might just as well ask the Ethiopian to change his skin as to change radically his social and religious ideas." This is the voice of a statesman.

The institution of an Imperial Bureau of Anthropology is a matter of particular importance to medical men. How many there are now abroad amongst subject and native races who would willingly carry out a series of most useful observations if only they knew in what direction they should turn their spare energies and interests. How many there are now returned home who recognise the opportunities they missed because they did not have the key to the various customs and practices they saw amongst the natives around them, or because they believed that all they saw was already well known. None are so well qualified from their education and none have so many opportunities [illegible] making anthropological observations as medical men. To them an Imperial bureau would be of the greatest utility. The interest of medical men will be the more readily enlisted in the scheme of such a bureau, seeing that it is intended, not only to embrace a study of primitive races, but to collect and systematise all pertaining to the physical constitution of the British race both at home and abroad. The question as to whether or not physical deterioration of the race is taking place has still to be answered. All at present is guess-work. A physical census of the present generation must be made to obtain a basis by which future observations may be measured. The medical examination of school children, which Mr. ASQUITH estimates must cost the country £260,000 per annum, will provide most useful data for this purpose. But the necessity of a census of the national physique will not thereby be rendered less urgent. The Universities of Cambridge and Oxford have established boards of anthropological studies, with the power of granting diplomas to those who have qualified by studies under their direction in prehistoric and historic anthropology and ethnology (including sociology and comparative religion, physical anthropology, and psychological anthropology). While the students at Oxford and Cambridge are thus provided for, no opportunities are given to students in London. Yet in London the means for study are perhaps the finest in the world. The collections in the British Museum and in the Museum of the Royal College of Surgeons of England, the libraries of the Royal Anthropological Institute and Geographical Society provide all that is needed, and more, for the education of students of anthropology. It was hoped by many that the University of London would establish a board of studies similar to that of the older universities, but when the attempt was made some years ago the board which resulted was not one in anthropology but one which has failed to attract London students—viz., the board of human anatomy and morphology. It is proposed that the Imperial Bureau of Anthropology should be empowered to grant diplomas to its students—a boon which would be appreciated by students not only in London but throughout the country and colonies.

◆

The Vaccine Treatment of Acne.

MANY of the diseases of the skin are especially suitable for the accurate estimation of the value of new methods of treatment, for the daily variations are open to examination Should the inflammation increase, the fact is at once patent, for the redness and the dilated vessels are visible, and there is no need to employ physical methods to ascertain the fact; on the other hand, should the inflammation subside, the diminution of the vascular supply of the part is at once evident. Even the amount and character of the exudates from the vessels of the skin can be appreciated in a way impossible with diseases of other and deeper structures. One of the newest and most valuable methods of combating microbial disease is by the administration of vaccines, and some of the diseases of the skin have proved very amenable to this mode of treatment. The vaccine treatment has yet another value; it may serve to determine etiological questions. If a patient is suffering from a disease in which the presence of a micro-organism has been detected, the effect of the employment of a vaccine may suffice to determine whether that micro-organism has or has not a share in the production of the disease. Moreover, when two, organisms are found to be present in many cases of an affection, the administration of a vaccine prepared from one or other of these microbes may indicate the relative importance of the two microbes as etiological factors.

In the present issue of THE LANCET appears a paper by Dr. ALEXANDER FLEMING, of St. Mary's Hospital, on the Etiology of Acne Vulgaris and its Treatment by Vaccines. The cause of acne has been discussed for many years, but without the formation of any very definite ideas as to its real mode of production; it is sufficient to read the long list of causes mentioned in most of the text-books to recognise that the essential cause is not among them, although and doubtlessly each of them may occur in one way or another as an etiological factor. UNNA in 1893 was the first to demonstrate a special bacillus in cases of acne and he named it the acne bacillus. He found it constantly present in sections and smears of comedones and acne pustules; moreover, it was the only organism which could always be found, and it was present in greatest number in the deeper parts of the comedo. Four years later SABOURAUD described the bacillus as occurring in sebaceous plugs of seborrhœic skins, and he claimed that it was the cause of seborrhœa and of alopecia areata. It is probable that this inclusion of alopecia areata in the effects of Sabouraud's bacillus retarded the recognition of its etiological value in seborrhœa and acne, for the clinical characters of alopecia areata are sufficient to exclude it from a group containing the two other diseases. The general feeling among dermatologists with regard to Sabouraud's bacillus was that, though it was possible that it was the cause of seborrhœa, it was not proved that it had anything to do with alopecia areata or with acne. In 1899 GILCHRIST of Baltimore described a bacillus constantly found in acne, and in one-third of the cases it was obtainable in a pure culture from acne lesions. He named the organism "bacillus acnes," and looked upon it as differing from Unna's bacillus, but most of those who have examined the question agree in thinking that Gilchrist's bacillus acnes is identical with Unna's acne bacillus and with the bacillus described by SABOURAUD. The absolute regularity with which the bacillus can be found in cases of acne vulgaris suggests an etiological relationship between them, but mere coincidence of occurrence cannot prove that the bacillus is the cause of the disease. However, the opinion is distinctly gaining ground that the bacillus is the *causa causans* of acne, although there may be other etiological factors. A further problem awaits solution. Even if it be admitted that the acne bacillus gives rise to the comedo, is it also the cause of the pustules which are the almost invariable accompaniment of a case of acne? Can the acne bacillus cause suppuration by its own unaided efforts, or does it need to invoke the aid of ordinary pyogenic organisms to give rise to acne pustules? Opinions differ. UNNA considered that the bacillus was the cause of the pustules, for in his opinion the histological characters of the pustules differed from those found in ordinary staphylococcic pustules. SABOURAUD thought that the suppuration was due to a secondary infection with pyogenic organisms. GILCHRIST found that even from the pustules a pure culture of the bacillus acnes could be obtained in a good proportion of the cases examined, and therefore he considered that the pustules as well as the other lesions of acne were caused by the bacillus. WHITFIELD from his own researches concluded that the comedo is caused by the acne bacillus, but he looked upon the pustule as due to a secondary staphylococcic infection. In this position the matter rested; without some fresh light, some fresh method of investigation, it seemed to be impossible to give a decisive answer to either question: first, whether the acne bacillus causes the comedo, and secondly, if it does cause the comedo, does it also cause the pustule?

The answer to these questions may be supplied by the vaccine method of treatment, and, if so, it is to be found in Dr. FLEMING'S paper to which we have already referred. In the first place, he concurs in the almost invariable existence of the bacilli in the comedones, and he finds that they are also almost always present in the pustules. The bacilli grow with difficulty on artificial media, but in many cases a pure culture was obtained by Dr. FLEMING even from the pustules. So much for the constancy of the organism. A pure culture of the bacillus proved capable of producing a folliculitis on the forearm of a susceptible person. In five days definite pustules appeared, and when the pus from them was examined only the acne bacillus could be seen. Further evidence is to be found in the fact that the serum of patients afflicted with acne agglutinates the bacillus in some cases. Sir ALMROTH WRIGHT showed in 1902 that carefully prepared vaccines derived from the infecting organisms produce a definite beneficial effect. Dr. FLEMING'S chief contribution to this important subject is the showing that a vaccine prepared from the acne bacillus alone, or in certain cases in combination with a staphylococcus, is capable of effecting a remarkable improvement in the condition. In most cases of acne a stock vaccine of the acne bacillus gives extraordinary results when employed in suitable doses; an excessive dose is followed by a negative phase and the outbreak of a fresh crop of pustules; when the dose is reduced sufficiently improvement follows. In some cases it appears to be necessary to prepare a vaccine from the acne bacillus present in the individual patient, but this is exceptional. From a consideration of these facts, described in detail in Dr. FLEMING'S paper, we are justified in concluding that the acne bacillus is the essential causative factor in acne vulgaris, and that by its own unaided efforts it is capable of producing a pustular eruption, but that in some cases the suppuration may also be caused by a secondary staphylococci infection. The investigation conducted by Dr. FLEMING is very complete, and in our opinion practically settles a question which has for many years disturbed the dermatological world.

Immunity and Immunisation.

"THE physician of the future will be an immunisator." Such is the text or quotation—perhaps in accordance with the fashionable terminology of the day we ought to say "auto-quotation"—which adorns the title page of the newly issued volume of collected studies by Sir A. E. WRIGHT and his fellow workers in the field of immunity,[1] the appearance of which may serve as an occasion for reviewing the progress made in recent years in our knowledge of the mechanism of resistance to infective disease and of the therapeutic measures founded upon it. In one sense, indeed, the statement quoted above is but a truism, for the more we learn that diseases are due to the action of invading germs, the more it necessarily follows that the labours of the physician must be directed to strengthening the resistance of the body against these parasites; and whether he pursue this end by rest and careful dieting or by the methods more recently introduced for directly stimulating the defensive mechanism he is equally an immunisator or cultivator of resisting power. But we shall not be mistaking the meaning of the distinguished editor of the work in question if we take his dictum in the narrower sense that the physician of the future will operate mainly by means of vaccines and allied remedies. It is therefore to this aspect of the question that our attention must be directed.

Our knowledge of the means by which the body resists the attacks of parasitic germs was inaugurated by the work of METCHNIKOFF on the phagocytic powers of the leucocytes, work which gave rise at first to very lively controversy. The discovery made by BEHRING, ROUX, and KITASATO that the poisons of certain bacteria are neutralised in the body by antagonistic bodies elaborated in response to their action, and the observations of PFEIFFER and others on the destruction of pathogenic germs by means of the serum of the blood, seemed for a time to throw the phenomena of phagocytosis into the background, but recent investigations have once more brought METCHNIKOFF'S views into prominence. The discoveries of the French school that the serum in some way facilitates the process of phagocytosis have been extended by the fascinating researches of Sir A. E. WRIGHT, who has given to these properties not only a local habitation in certain hypothetical bodies but has also bestowed on the latter the attractive name of opsonins. Thus, while in the case of certain germs, of which those of diphtheria and tetanus are the types, the main resistance of the body is effected by antitoxins, and in a few other instances, notably in the case of the bacilli of cholera and enteric fever, destruction of the parasites is effected mainly by substances which directly destroy the organisms, in a large number of cases immunity appears to be due in great part to the interaction of serum and leucocytes, the former in some way preparing the bacteria for ingestion by the latter. Such is the mode of resistance, so far as is at present known, to the staphylococci and allied germs, to the bacillus of tuberculosis, and to many other pathogenic organisms. In enumerating, however, the antitoxins, opsonins, and bacteriolysins of the blood we have probably not exhausted the number of bodies which take part in immunity. If we disregard the agglutinins, which probably take some part in the process of destruction of bacteria, we can yet hardly doubt that, at all events in the case of those germs which give rise to a local form of disease, the cells of the tissues themselves take part in the process of resistance, while some of the endothelial cells appear to possess powers of acting as phagocytes. Of the factor of cellular resistance it would seem that little or nothing is at present known. A still different property of the serum to which attention has recently been directed in our columns by Dr. F. L. GOLLA[2] is its power of inhibiting the action of trypsin. It is too soon, however, to speculate far as to the possible influence of this property in producing immunity.

---

[1] Studies on Immunisation and their Application *to the* Diagnosis and Treatment of Bacterial Infections. By Sir A. E. Wright, M.D., F.R.S., Director of the Department for Therapeutic Immunisation, St. Mary's Hospital, &c. London: A. Constable and Co., Limited. 1909. Pp. 490. Price 16*s*. net.

With regard to the other bodies mentioned—hypothetical bodies, it is true, since no one of them has ever been isolated, though we know that some of them can be precipitated along with certain of the albuminous constituents of the blood—they are either naturally present in the serum or are poured into it in response to the action of the parasites and their poisons. It is upon this last phenomenon that modern methods of immunising treatment are based, since it is possible by injecting harmless doses of dead germs or of their toxins to increase the quantity of immunising bodies present in a living animal, and thereby to create an artificial resistance which may serve either as a prophylactic against the attack of the parasite in question or may enable the body when already infected to contend successfully with the invaders. The results obtained in some directions are most encouraging. In cases of local affection due to staphylococci a very useful weapon has been added to our armoury, and in tuberculosis marked good may be done in suitable cases by means of the various forms of tuberculin.[3] In other chronic infections we may reasonably hope that equally important results will be obtained. But the question of the value of vaccines in acute infective diseases is also one of great interest. It would seem at first sight that when the pathogenic bacteria have invaded the blood stream and have thus been spread throughout the whole system it would be worse than useless to inoculate an additional dose of the causal organism. On the other hand, it has been suggested that the blood stream is not a favourable medium for the formation of antibodies, and that the introduction of a dead culture into the subcutaneous tissue and thereby into the lymphatic spaces may give rise to increased resisting powers. On this point the evidence is not at present complete, but attempts have been made both in enteric fever and in pneumonia to influence the course of the disease by this means and some favourable results are recorded.

No part of Sir A. E. WRIGHT'S work has been more interesting than that connected with the attempt to measure the degree of immunity existing in a patient by an estimation of the opsonin-content of the blood serum. A most important change in procedure, fraught with benefit to innumerable patients, has resulted from this study—namely, the use of much smaller doses of tuberculin than had previously been employed, as Dr. A. J. LANDMAN points out in another column this week. The right value of a remedy which had fallen into undeserved disrepute owing to mistakes in the mode of its administration has now been established, and the prospects of relief or cure in suitable cases are definitely increased. Whether the opsonin-content can in reality be held to constitute a true measure of the total resistance may be open to doubt, since the complex nature of the factors at work in immunity is obvious. When it was first discovered the agglutinating power of the serum was thought to afford such a criterion, and it undoubtedly did in many instances correspond to some extent with the patient's resistance, yet its value as such is now doubted, and it may be that the opsonin-content of the serum will equally be found wanting. More important at the present stage of our knowledge is the doubt that has been thrown on the accuracy of the methods available for estimating this element in immunity. Apart from the possible influence of the personal factor in the process of enumeration of ingested germs it has been shown that successive series of leucocytes acted on by the same serum and fixed on the same slide may reveal serious divergencies in their phagocytic action, and a momentous source of error may thus arise unless an impracticable number of these cells are counted, while, as Dr. LANDMAN states, the complexity of the method is in itself a bar to its use by any but experts. It can hardly be denied that at the present time less attention is being paid to such estimations than was the case a short time ago. Perhaps, however, the pendulum may have swung too far in the negative direction, and time may yet evolve an improved method of procedure and rehabilitate this test of immunity In any case, a most interesting field of research has been worked, and the brilliant observations made by Sir A E WRIGHT and his pupils, while they have thrown lustre on British science, have opened a new chapter in the history of medicine.

Annotations.

"Ne quid nimis."

ALCOHOL IN HOT-CROSS BUNS

THE decline in the sales of the hot cross bun, which appears to be admitted by the baking trade, is of little dietetic import seeing that, except for the addition of spice and currants, the hot cross bun is practically bread and is similarly prepared Fast nowadays has for the most part yielded to feast and there is no office left for the Good Friday bun The discipline of its consumption no doubt offered in bygone days moral and physiological advantages, but the times have changed and the bun has changed in them There is one interesting point in regard to the composition of a sample hot cross bun which we have brought to light in a recent analysis, and that is that it contained quite an appreciable quantity of alcohol Thus a bun weighing 2½ ounces was found to contain 7 2 grains of alcohol, or 0 68 per cent This amounts to the quantity of alcohol contained in a third of a fluid ounce of light beer, so that 20 buns would contain approximately as much alcohol as a tumbler of beer (8 ounces) This quantity, though appreciable, is of course very small and such as need give no concern to the anti alcoholist The fact is that the hot cross bun, like bread, is a partially fermented food, yeast being used to make it light, and the normal outcome of this process is a little alcohol It is, however, somewhat surprising that the alcohol formed is not completely dissipated by the heat of the oven, but doubtless owing to the tenacious character of the dough some of the alcohol is imprisoned The albumin glaze on the exterior of the bun may serve also to retain the alcohol Good buns, however, if need be, can be made without yeast and a *strictly teetotal bun obtained* The complete analysis of the bun compared with bread is of interest, the results being as follows —Water, 30 82 per cent , alcohol, 0 68 per cent , starch, 52 63 per cent , protein, 9 12 per cent , fat, 5 40 per cent , sugar, 0 85 per cent , and mineral matter, 0 50 per cent Bread contains 10 per cent more water, traces of alcohol, about the same amount of starch, 3 per cent less protein or nitrogenous substances, 4 per cent less fat, and approximately twice the amount of mineral salts Owing chiefly to a smaller proportion of water, the bun, weight for weight, contains a rather larger amount of *nutritive substances than bread, the occurrence of a relatively* large amount of fat, due to the addition of butter in the bun, rendering it a fairly complete food containing reparative and energising materials alike

THE MEDICAL INSURANCE COMMITTEE.

A MEETING of the Medical Insurance Committee was held at the offices of the British Medical *Association on Thursday*, April 1st, when the report from the secretary and agent showed that all the business done by the Committee was progressing satisfactorily if slowly, and that especially the undertakings as to life insurance had substantially increased The renewals of policies under employers' liability have involved a great deal of work, at least 75 per cent requiring some change in the conditions of the policies, and a voluminous correspondence was the inevitable accompaniment The total number of policies dealt with represent 2540, of which 2480 are running As a result £160 have been distributed among the insurers, who have also been *relieved by the agency of all possible trouble and* inconvenience *Allowing for sundry liabilities*, but not for managerial expenses, a small surplus of £52 remained as the net result for the working of the year 1908. The Committee are not discouraged by the modest nature of their success and propose with the cooperation of the Guardian Assurance Company to continue the work Offers which have been made to them by other offices than the Guardian have let them see clearly that medical insurance has a future before it the importance of which will be great entirely according as many medical men avail themselves of a united scheme We may again remind our readers that communications on this subject may be made to Mr Guy Elliston, general secretary of the British Medical Association

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

WE are pleased to offer again our congratulations to Sir Richard Douglas Powell on his re election as President of the Royal College of Physicians of London The very large majority by which the election was carried proved the continued confidence and approbation with which he is regarded by the College This is all the more significant in *that important matters are under discussion, notably the* negotiations which are proceeding in connexion with a scheme to render a London medical degree reasonably accessible to all those students who are pursuing their studies in London, an event which Sir Richard Douglas Powell has truly at heart The sagacity and tact which have always characterised his actions will be particularly valuable at the present juncture, and we consider that the College evinced sound judgment in again electing him to the office which he has so ably held for the past four years

CANNIBAL MEDICAL LITERATURE

IN an annotation which appeared in THE LANCET of March 20th the Battaks (pronounced "Battas') of Sumatra were described as low savages addicted to cannibalism. But it is only fair to these despised people to point out that they possess a literature, and that their literature is medical The Battak manuscripts of which there are a few specimens in the Marsden library at King s College (University of London), are curious examples of the most primitive form of book In his classic work on Sumatra, published in 1811, William Marsden thus refers to this literature of cannibals "Their books are composed of the inner bark of a certain tree, cut into long slips, and folded in squares Their contents are little known to us The writing of most of those in my possession is mixed with *uncouth representations* of *scolopendra* and other *noxious* animals and frequent diagrams which imply their being works of astrology and divination " M Claine, reporting in 1892 on a Battak MS , of which the late Dr G W Leitner reproduced a copy in photogravure in the *Imperial Asiatic Quarterly Review* (1892), describes it as referring to some plague The book was presented to Dr Leitner's much abused Oriental Congress at the time, and was submitted by him to Pundit Janardhan, an eminent Vaidak physician of Lahore The writer of this article was at the same time busily employed in unearthing the Battak manuscripts in the Marsden Library at King s These, with Captain Cook's original diaries and other treasures of price, were soon found in a large box, which had never been lost, but which had suffered neglect owing to its very obviousness In no long time the learned Pundit doctor of Lahore replied in the pages of Dr. Leitner's *Review*. We in England had been possessed by the idea that the Battak bark books contained a definite adumbration of the theories of Pasteur. The little twiddles, painted in some black pigment on the bark, were held to be what were then called "germs." Dr. Janardhan entirely agreed with us, but he pointed out that the Battak illustrations were borrowed from ancient Hindi books, as is often the case where primitive authors are at a loss to find artistic comments on their ideas. He declared, in reference to the ancient Sanskrit medical books from which the Battak cannibals copied their illustrations with an infinite neatness: "Whatever people may choose to say about the discovery of bacilli and microbes as a new thing (in 1892) in medical science, it is quite evident that the principle of this discovery was many ages ago given in our Sanskrit books of medicine; and the details, elaborated and tabulated, can be produced to prove this statement." But the Sanskrit illustrations in question really refer to worms, not to germs. In India diseases are often traced to a "Kira" or worm, and the Battak pictures really depict a number of these. Two very large ones, with fangs and antennæ, are supposed to produce respectively cholera and diarrhœa and phthisis. Another smaller worm is held to set up leprosy. Many worms are held to be invisible. The orthodox number of worms is 20. Their excess in the human being produces certain diseases, their defect certain others. They are mentioned in all the old books of Hindi medicine. It is curious to note that leprosy arises from a worm, in the opinion of the Sanskrit medical authorities. But from the brutal Western point of view a worm is *not* a microscopic germ. Nor are we inclined to be cajoled into a bacterial theory of the origin of disease having been familiar to the ancient Hindoos from such evidence as the learned Pundit has so far put before us.

THE OPERATIVE TREATMENT OF FRACTURE OF THE BASE OF THE SKULL.

THE current treatment of fractures of the base of the skull is purely expectant—rest, purging, and the application of cold. In the *Intercolonial Medical Journal of Australasia* Dr. D. Murray Morton, surgeon to St. Vincent's Hospital, Melbourne, has called attention to the value of operative treatment in many cases which seem hopeless. The immediate danger in severe head injuries is principally due to compression from extravasated blood. Harvey Cushing in Keen's "System of Surgery" admirably states the position thus: "In any serious cranial injury in which unconsciousness has been present from the first, subdural bleeding is taking place either from the fracture itself or from some laceration of the brain." With regard to basal fractures he says: "One cannot hope to disclose the point of injury or to check the oozing which may be taking place, but the chief indications in the face of compression symptoms are to bring relief by decompression and to furnish a means of escape for the extravasating blood. When the pressure phenomena have not advanced to the point of seriously implicating the bulbar mechanism expectant treatment may be resorted to. If, however, there is evidence of failure in this mechanism it is inadvisable to delay intervention." Dr. Morton advises that every grave head injury, and especially basal fractures, should be placed under close supervision, and that whether fracture of the base is diagnosed or not a decompressive operation should be performed if there are serious or increasing symptoms of compression. In the absence of symptoms indicative of hæmorrhage from the middle meningeal artery or of other focal symptoms, and probably in all cases of fractured base, the occipital route is recommended by Cushing and gives the easiest and safest access. It affords efficient drainage and a substantial buttress of muscle to prevent hernia cerebri. The following case is an example of the advantages of prompt operation. A clergyman was admitted to St. Vincent's Hospital on Sept. 23rd, 1908. He had been knocked down by a large motor-car and was picked up unconscious. The temperature was 98° F., the pulse was 80, good, and regular, and the respirations were 22 and easy. Across the right upper eyelid was linear extravasation and there were some abrasions of the nose. In the left occipital region was a contused wound with considerable swelling around it from extravasated blood. The pupils were equal, active, and moderately contracted. The knee-jerks were increased. Vomiting, with traces of blood, occurred soon after admission. The pulse gradually became slower and irregular, falling as low as 54 about half an hour after admission, and the patient was lapsing into coma. The head was shaved and the scalp was sterilised. The occipital wound was freely enlarged and a linear fracture of the skull was found and traced upwards towards the vault on the left of the middle line and downwards towards the foramen magnum. The skin and muscles were freely reflected from the occipital bone and the fracture was found to increase in width towards the base and to exude dark blood freely. As the trapezius and complexus muscles were reflected small scraps of brain tissue were found in their substance. A small trephine was applied over the horizontal table of the occipital bone with its inner margin at the fracture and a disc of bone was removed. The dura mater was opened and deeply blood-stained cerebro-spinal fluid flowed freely. The cerebellum was contused and lacerated. A small rubber drainage tube was cut longitudinally and passed with the resected aspect downwards towards the foramen magnum. The wound was closed with silkworm gut and horsehair sutures, and the tube was fixed by a suture. During the operation the pulse improved in volume and became steadier. At the conclusion of the operation the extravasation of the right upper eyelid, which at first resembled a pencil mark, had increased to an ecchymosis of about the size of half a walnut. It was inferred that the fracture passed from the foramen magnum through the right middle fossa and then ran forwards in the anterior fossa into the orbital plate. On recovery from the anæsthetic the patient was restless and irritable but slept in the intervals. He was able to speak and insisted that he should be up and at his work. In the evening the temperature rose to 100·2° but afterwards was normal. There was copious discharge of blood-stained cerebro-spinal fluid for three days and then of clear fluid, and recovery ensued.

THE INTELLECTUAL ACHIEVEMENTS OF THE BLIND.

THREE months ago the centenary of the birth of Braille, the inventor of special type for the use of the blind, was celebrated. Braille had been blind from the age of three. In 1828 he was appointed professor in the Institution Royale des Jeunes Aveugles. The pioneer in the education of the blind by development and training of the sense of touch was Valentin Haüy, who founded a school in 1784. For reading purposes he used only ordinary type printed in relief. Reading by this method was a tedious process and no greater benefit was ever conferred upon these afflicted people than the invention of the Braille system. How great a success it has been and how much it is appreciated is shown by the fact that the Bibliothèque Braille now contains over 25,000 volumes. An instance of extraordinary intellectual development and achievement in spite of loss of sight, hearing, and speech is found in the now well-known case of Helen Keller. Another noteworthy achievement by a blind young man is a book in three volumes, comprising 1250 pages, entitled "Les Sources et l'Évolution des Essaies de Montaigne," by Pierre Villey (Paris: Hachette, 1908). The author has been blind since the age of four and a half years. At the age of eight he commenced the study of Braille type. He was educated at the Institution Nationale des Jeunes Aveugles in Paris and at the École Normale Supérieure. Attracted to the study of history and literature, he undertook the important task of trying to arrange Montaigne's "Essays" in chronological sequence and to trace the thoughts and allusions, so far as these were borrowed, to their original sources. With the help of a secretary he wrote out the whole of the essays in Braille type. With these 20 volumes at his disposal he compiled three annotated indices of the chief ideas presented by the author, the characteristic images, expressions, and so on, and the historical examples and anecdotes. He then obtained and had read to him all the possible contemporary sources of Montaigne's inspiration. That the result is a worthy contribution to literary history is shown by an appreciative criticism in the *Revue des Deux Mondes* of Feb. 1st last. The number of the same review of March 15th contains an interesting article by M. Villey upon Intellectual Work amongst the Blind which will well repay perusal by those who are concerned in the alleviation of these afflicted people.

EPIPLOITIS FOLLOWING THE RADICAL CURE OF INGUINAL HERNIA.

IN the *New York Medical Journal* of Feb. 6th Dr. C. Greene Cumston has described an unusual sequel of the radical cure of inguinal hernia—namely, epiploitis. The operation was performed on a man, aged 24 years, for right inguinal hernia. The sac contained only omentum, a large mass of which was resected and ligatured with kangaroo tendon. The operation was easy and rapid, but on the following day the abdomen was distended and the patient complained of pain. On account of the distension respiration was somewhat difficult, although it was unaccompanied by pain. On the third day the patient was very restless, but the temperature was not elevated. The bowels acted after administration of an enema, but the distension continued. The condition remained about the same until the ninth day, when the temperature rose to 102°F., and the abdomen became still more distended and tender on percussion. The tongue was dry and the patient was more restless. A swelling was felt in the right hypochondrium, extending from the costal border to the iliac fossa and most marked under the cicatrix of the operation wound. The latter was in perfect condition and the stitches were removed. The swelling was elongated in shape, with its long axis running vertically from above downwards, and appeared to be in direct contact with the abdominal wall. It felt resistant and immovable, and was dull all over. It was painful and the pain was increased by palpation. The abdomen was still distended and the constipation was obstinate in spite of the administration of high enemata. The temperature was 104° and the abdominal facies was present. Epiploitis was diagnosed. Ice-bags were placed on the abdomen and a pill containing two centigrammes of colloid silver was given four times daily. At the end of 12 days the temperature reached normal. The bowels began to act normally and the pain and swelling diminished. The colloid silver was continued for three weeks. Seven weeks after the operation the patient was discharged in perfect health. There are several forms of epiploitis. There is a benign form which shows itself by slight tumefaction and very little pain and from which recovery is rapid under rest in bed. Occasionally epiploitis manifests itself by the ordinary symptoms of intestinal obstruction. Sometimes suppuration occurs and manifests itself by a high temperature and the presence of an intra-abdominal fluctuating mass, and symptoms of intestinal obstruction (abdominal distension and fæcal vomiting). In such cases secondary laparotomy and treatment of the condition present, such as opening and draining an abscess or breaking down adhesions, which cause intestinal obstruction, may be necessary.

THE "AFTER-CARE" ASSOCIATION.

WE have before us the report for the year 1908 of the council of the After-Care Association for Poor Persons discharged recovered from Asylums for the Insane. The better known this admirable association becomes the more widely does its sphere of usefulness extend, and we note that in the year reported on 610 visits were paid, more than 4060 letters were written, and 620 interviews took place at the office of the association. A large amount of personal care is devoted to each individual case, and it is the constant endeavour of the association to find suitable work and a suitable environment for the convalescent patients to whom its care is devoted. It is a fact that is frequently overlooked that recently discharged patients are rarely, if ever, sufficiently well to resume the battle of life as if nothing at all had been the matter with them, and the result is that too often many rapidly break down again. To avoid this the association seeks to relieve the discharged patient from the worry of looking for employment and to make sure in each individual case that the work when found is not in excess of the patient's capacity. The work done by the association in this way is worthy of all possible commendation and support. We notice with pleasure that at several institutions offertories are made in their chapels in aid of the association, and we hope that by this means, as well as by the method of subscription, the association may be assisted still further to extend its field of beneficent usefulness.

PERIODIC FAMILY PARALYSIS AND EPILEPSY.

THE etiology of periodic paralysis, that condition in which a transient flaccid paralysis of a limb or limbs recurs at irregular intervals and is associated for the time with loss of all electrical reactions in the groups of muscles concerned, is still exceedingly obscure. A case was recorded as long ago as 1882 where the patient's father was also affected, and a brother was an epileptic. This same patient has been followed carefully, and the remarkable fact ascertained by Dr. Bornstein—whose paper will be found in a recent number of the *Deutsche Zeitschrift fur Nervenheilkunde*—that his periodic paralysis ceased five years ago, to be succeeded by attacks of typical epileptic vertigo and other epileptic equivalents of a visual character. Dr. Bornstein reports a further case in a boy aged 14 years, mentally and physically somewhat backward, who from the age of two and a half to four years suffered from convulsive epileptic attacks with loss of consciousness. Since the age of eight he has been the subject of recurring paralyses of his limbs, appearing at highly irregular intervals, usually during the night, and lasting from a few hours to a day or a day and a half. At no time is there any loss of consciousness in these paralytic seizures. Sometimes the whole musculature of trunk and limbs is affected; sometimes the latter are more affected on one side than the other; sometimes certain muscular groups, such as flexors or extensors, are singled out. The deep reflexes are usually diminished, but the knee-jerks have always been found brisk, although there is no extensor response on stimulating the sole of the foot.

almost impossible to define accurately the time relation between the *raw* and *stored* water. Thus the "intakes" are sometimes closed, the volume of water abstracted for storage purposes varies from time to time, the method of circulating water through the storage reservoirs depends on circumstances, and the amount of water in the reservoirs varies greatly throughout the year.

Source of raw river water.	Description of stored water.	Nominal number of days' storage.
River Lee at Ponders End.	Lee stored water.	58·44
River Thames between Sunbury and Hampton.	Chelsea stored water.	15·09 Based on the 1906–07 supply.
	Lambeth stored water.	14·35
Almost entirely River Thames above Bell Weir.	Staines stored water.	95·00

Dr. Houston proceeds to state that his chief object was to ascertain whether the number of days' storage capacity which it is necessary to provide in avoidance of shortage of water-service under unfavourable conditions of flood and drought may be held to suffice in the matter of satisfactorily securing safety of the water in an epidemiological sense. In a word, does storage for *quality* require more accommodation than the obviously necessary storage for *quantity?* In the conclusions at which Dr. Houston arrived at he accepts personal responsibility so far as they are controvertible.

The second section of the report describes the bacteriological results and commences with a table showing the number of bacteria grown from the raw and stored water respectively on various media. This shows that the stored waters contained very few "total" bacteria in comparison with the raw waters, the reduction being especially well marked in the case of the Lee stored water.

> As regards ratios, the results seem to indicate that the reduction in the number of bacteria in the stored as compared with the raw waters, tends to be *proportionately* less in agar at 37° C., than in gelatine at 20 22° C.; the converse (except as regards Lambeth) holding true when the bile salt agar and ordinary agar results are compared In other words, although storage apparently leads to a rather smaller *proportionate* reduction of organisms capable of growing at blood-heat than of microbes of all sorts, *proportionately* as well as actually, fewer blood-heat organisms are able to grow in bile-salt agar than in agar.

The results for bacillus coli are next given and afford striking reading.

> *Thames water.*—About 50 per cent. of the samples of *raw* Thames water contained typical B. coli in one-tenth of a cubic centimetre. Of the Staines, Chelsea, and Lambeth *stored* water samples about 34, 43 and 16 per cent. respectively contained *no* typical B. coli in one thousand times as much water—namely, in 100 cubic centimetres. Or, preserving the same order, only 66·2; 57·2 and 83·7 per cent. of stored water samples yielded positive results in 100 cubic centimetres, and only 32·5; 32·5 and 51·2 yielded positive results in 10 c.c. of water. Thus on the foregoing basis of comparison, the Lambeth stored water was about one hundred and the Staines and Chelsea stored water between one hundred and one thousand times less impure than the *raw* Thames water.
>
> *Lee water.*—Over 50 per cent. of the samples of *raw* Lee water contained typical B. coli in one-tenth of a cubic centimetre.
>
> As regards the Lee *stored* samples, actually as many as 67·4 per cent. yielded negative results with 100 cubic centimetres and only 32 5 per cent. yielded positive results in that amount. Thus on the foregoing basis of comparison the Lee *stored* water was over one thousand times less impure than the *raw* Lee water.

Dr. Houston proceeds to show that as bacillus coli is more resistant than the typhoid bacillus it is presumable that the same results would apply to the latter organism if it were present, a presumption which has the support of his former research, in which he added typhoid bacilli to raw river water and found that 99 per cent. of them died after storage for a week. The results obtained in the present research with the bacillus enteritidis sporogenes are next described and show that storage caused a great diminution in that organism. In the case of the *raw* Lee water, 36·5 per cent. of ten cubic centimetre samples gave a growth, whereas it was not cultivated from a single sample after storage of the water. Further, on taking the Lee averages as a whole it was found that there was a 97 per cent. reduction of all bacteria growing at blood heat, and of those capable of growing on a bile-salt medium (chiefly excremental bacteria). Dr. Houston infers from this that a *raw* water which has uniformly undergone such a remarkable metamorphosis is almost certainly incapable after filtration, possibly (perhaps even probably) antecedent to filtration, of causing epidemic disease. Nevertheless, he regards storage of water as a pre-filtration precaution of the utmost value, not as a substitute for filtration. But in advocating sufficient storage accommodation he would much prefer the use of insufficiently stored water to the use of *raw* river water for filtration purposes. He next considers the ratios in the number of typical bacillus coli to the total number of bacteria found in the raw and stored waters, figures into which we need not enter further than to record that the worst results of the latter were on a level with the best results of the former waters.

The third section of the report deals with the chemical results from which we need only make brief extracts:—

> It will be seen ...... that in all cases, the *stored* waters contained (on the average) less ammoniacal nitrogen, and less oxidised nitrogen; absorbed less oxygen from permanganate, and were less turbid, brown-coloured and "hard" (total hardness) than the average of the corresponding *raw* waters.
>
> As regards the albuminoid nitrogen test, the average Lea stored water did not differ from the raw water, the Staines and Lambeth stored waters suffered an apparent increase, and only the Chelsea showed a reduction. In this connexion it must be remembered that the albuminoid nitrogen is an empirical test, and that it appears that a *stored* water may yield a higher ratio of ammonia to total organic nitrogen when boiled with alkaline permanganate than does a *raw* water.
>
> A considerable number of laboratory experiments were also carried out to ascertain whether the *stored* waters were more easily filtered than the *raw* waters. The results are not given here as the method employed was only a rough and ready one. But they sufficed to show, under the conditions of experiment employed, that in the *absence* of an excessive development of algae, stored water was much more amenable to filtration than *raw* water. Under normal conditions (i.e. in the absence of algae) the use of *stored* water prolongs the life of a filter bed, often to a remarkable extent. In this connexion it may be pointed out that lengthening the life of filter beds is not only economically advantageous, but of epidemiological importance. For it is obvious that with a given filtration area the more filter bed area there is in active and efficient operation the better the results are likely to be. Unfortunately, however, it must be added that when algae develop in the storage reservoirs to an abnormal extent the *raw* river may be much more easily filtered than the stored water. To a considerable extent the developments of algae in storage reservoirs may be controlled by the use of copper sulphate, &c. Nevertheless, the use of chemicals is not likely to be recommended and is to be deprecated indeed unless carried out under proper scientific control.

In his concluding recommendation Dr. Houston suggests that the use of mechanical filters in place of sand filters might overcome the difficulty of an excessive development of algae. He also adds a caution against applying laboratory results too closely to the case of reservoir stored waters, in which the growth and decay of animal life and other factors may considerably affect by a sort of "mass action" the fermentation and oxidation of river waters. *He* suggests that the question of cleaning out the mud deposited in reservoirs may assume more prominence in the future and that it may be advisable to pass the water through preliminary settling reservoirs before its systematic period of storage in the larger reservoirs. He enters a plea for the utility of chemical water analysis which has been minimised in some quarters of late, showing that in some instances it may be the only way of gauging the work done by bacteria.

Section IV. deals with the shape, size, depth, construction, and method of working storage reservoirs. Stress is laid on the importance of arranging inlets and outlets with a view to insuring free circulation of the water. The "continuous flow" method of using a series of small reservoirs is advocated as more scientific and economical than the "quiescent method" of using large reservoirs, in which they are filled, closed for a certain number of days, and then emptied. The question is discussed as to whether the Board would be best advised to store its river water on a basis of a minimum or maximum period of 30 days. Dr Houston points out that the former method would involve the construction of enormous and costly reservoirs, and suggests that the latter would be found efficient if provision were made against deterioration of stored water during periods of stress and storm, such as the installation of "roughing" filters or precipitation tanks to be used upon occasion between storing and filtration.

Sections V., VI., and VII. deal with certain qualifying considerations, alternative measures such as sterilisation and the disadvantages of storing, to which due weight is given, but none of which appear to present vital difficulties to Dr. Houston's scheme. Their consideration is followed by the final section on the advantages of storing and Dr. Houston's conclusions. He states his case with logical precision under the following five heads:—1. *Adequately* stored water is probably incapable of causing epidemic disease. 2. There is reason to believe that stored and subsequently filtered waters are in a better condition chemically and physically than unstored and filtered waters. 3. Adequate storage may lead to easier filtration and a resultant economy of cost. 4. Adequate storage will afford a continuous sense of security absent under conditions which make it impossible to examine daily samples of all water passing through the Board's 160 filter beds. 5. Adequate storage tends to wipe out the gravity of the charge that London's supply is derived chiefly from sewage-polluted rivers.

Finally Dr. Houston replies in words which we must quote in full to the question as to whether the results of the research justify the policy of storing all water before filtration.

> I venture to anticipate that it will be considered that this question has been answered satisfactorily in the affirmative.
>
> [illegible] water of inferior quality) a period inevitably follows during which the duration of storage of necessity falls short, it may be far short, of 30 days.
>
> There are two ways of coping with this difficulty: 1. To consider 30 days as a *minimum* period of storage. This would entail the construction of huge reservoirs at an unremunerative cost, capable of holding for more than 30 days a supply of water, in order to cope with the [illegible] 2. To consider 30 days a [illegible] t during times of stress and [illegible] of purification, *antecedent* to storage, or *subsequent* to storage but *antecedent* to final sand filtration, as have been briefly outlined in the concluding paragraphs of Section IV. of this report.

Dr. Houston's final conclusion is that *raw* river water should be stored *antecedent* to filtration, preferably for 30 days. The question of whether the 30 days' storage should be fixed on a maximum or on a minimum basis he has left unanswered, but he holds that if the former alternative be chosen the desirability of employing supplementary processes of water purification to tide over emergencies is worthy of consideration.

THE ROYAL COMMISSION ON THE POOR-LAWS AND RELIEF OF DISTRESS.

VI.[1]

THE REPORT OF DR. J. C. MCVAIL ON POOR-LAW MEDICAL RELIEF IN CERTAIN UNIONS IN ENGLAND AND WALES.

IN order to render complete the information upon which it was to base its report, the Commission caused to be undertaken, by investigators appointed on account of their special competency in relation to certain subjects, various inquiries of importance. It is not proposed to deal at length in this series of summarising articles with all of these special reports, for their gist has in many instances been made plain by reference to them in the Majority and Minority Reports, which in some instances have quoted freely from them. It will, however, be of interest to readers of THE LANCET to comment upon some of them briefly as they appear, when they are concerned with questions affecting the medical profession. But one report of a special investigator to which reference was made in THE LANCET of April 3rd, p. 993, demands more elaborate treatment. It has been issued in a Blue Book, which, including appendices, contains 338 pages of printed matter, and is that of Dr. McVail, county medical officer of Stirling and Dumbartonshire, who was instructed to "inquire and report on the methods and results of the present system of administering indoor and outdoor Poor-law medical relief in certain unions to be selected from a list drawn up by the Commission." Dr. McVail brought to this inquiry a mind trained by work and experience of a kindred character in Scotland, but unfettered by previously acquired knowledge of Poor-law methods in England and Wales, and he bases his conclusions upon conditions observed in a large number of typical unions, Metropolitan, urban, and rural, ranging north and south from Northumberland to Somerset and east and west from Norfolk to Montgomeryshire. It will be observed by those who peruse Dr. McVail's report that owing to the wide terms of the reference made to him and the extensive area covered by his investigations, the summary of his conclusions almost inevitably takes the form of a general scheme recommending measures of change affecting other branches of Poor-law work as well as that of medical relief. Dr. McVail, in drawing his conclusions, has been at the disadvantage of not knowing the nature of those at which the Commissioners themselves would arrive, and to which they were evidently guided to a large extent by the facts laid before them by himself and others. Indeed, as he himself observes (p. 17), "In making recommendations and suggestions as to possible alterations in the present system, it has been necessary to think of the subject first, on the assumption that the present local organisations will remain, and that improvements in detail only are to be considered, and secondly, on the hypothesis that there may be a fundamental change in the local authorities, or a transference to country or municipal administration of medical work, at present done under the Poor-law, the main object of such transference being development of the preventive as distinguished from the curative or palliative side of medical treatment." The sentence quoted will be found to contain a certain amount of not incorrect prophecy, for both the Majority and Minority Reports agree that there should be a fundamental change in the authority with a view to prevention and relief, a change which, if the Majority Report is followed, will institute a new local authority altogether, or which, according to the advice of the Minority, should lead to a "transference to county or municipal administration." The consideration of improvements in detail only is not likely to satisfy the Legislature, because the improvements in detail the need for which is urgent are too numerous and too far-reaching. It is a matter of observation, however, that the report of Dr. McVail reveals many possibilities of improvement well within the competency of boards of guardians and not implying substantial increase of expenditure on their part. As examples might be mentioned provisions for admitting to dormitories and sick wards the fresh air which is always at hand by unsealing windows and opening them; similar steps to secure the ventilation of closets and latrines; the authoritative regulation and better supply of hot water in reasonably comfortable bath-rooms; provisions for a reasonable individual use of towels and hair brushes; the instruction of the young in the use of tooth brushes, and the provision of these important aids to the sanitary toilet. Obviously the undesirable qualities of the present system which point to its drastic reorganisation in the opinion of the Commission are not inseparably connected with matters of detail of this kind, which, however, appear necessarily in the report of a medical investigator upon existing conditions observed from the point of view of practicable sanitary reform.

Dr. McVail divides his report into nine parts. Part I. is introductory, and, besides explaining the methods adopted by the investigator, contains statistics of pauperism in unions visited, particularly instructive with regard to the varying cost of pauperism, the expense of keeping the individual pauper, and the expenditure per head of the population upon poor relief. Part II. and Part III. [illegible] rural and urban workhouses [illegible] entitled "Certain Questions [illegible] Urban Medical Relief." I[illegible] insufficiency of medical attendance in sick wards and infirmaries Dr. McVail has had to draw a sharp distinction between rural and urban districts, and he points out that the effect of the repugnance to the "workhouse" observable in rural districts includes sick wards and infirmaries, so that in the country the majority of cases requiring medical care accept outdoor relief and refuse to come within doors. It need hardly be added that some of these require institutional treatment, and that to render it acceptable to them will be one of the results aimed at under whatever system takes the place of the present one and abolishes suffered universally more than males, probably owing to their more constant use of this foul water. Epidemic dropsy reappeared during the latter half of the year in an epidemic form. Dr. Pearse draws attention to the frequent occurrence of cases indistinguishable from cases of beri-beri; thus these showed deep-seated pain in the legs and calves, impairment or loss of knee-jerk, unsteadiness of gait, and cardiac trouble. Anæsthesia, which had not been noticed in previous outbreaks, occurred in the one under notice. Death occurred also, sometimes suddenly. It is apparently a communicable disease with an incubation of about three days.

---

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Feb. 27th (p. 633), March 6th (p. 706), 13th (p. 782), 20th (p. 859), and 27th (p. 935), 1909, respectively.

The report concludes with an account of the work of the department in the laboratories, the work carried out by the food inspectors, with other matters, and finally, various excellent sanitary reforms are suggested as regards privies, municipal cowsheds, and slaughter-houses. The provision for displaced population and for the removal of infectious cases to hospital is also at present wholly inadequate to the requirements. This is a most admirable report.

Burma.

Major C. E. Williams, I.M.S., the Sanitary Commissioner for Burma, furnishes the annual report for 1907. Since the retirement of his predecessor Colonel W. G. King, the offices of Inspector-General of Civil Hospitals and Sanitary Commissioner have been separated, Major Williams being appointed to the new post of Sanitary Commissioner to the province. With reference to the vital statistics, the total population, which in 1901 was 8,485,980, had increased by March 1st, 1908, to 9,731,233. There was an increase of births over deaths to the amount of 52,841; the registration of births and deaths, however, the Sanitary Commissioner shows, is capable of much improvement. As regards the rainfall, that in Lower Burma was much in excess of that in 1906, whilst in Upper Burma the contrary obtained, the latter year having showed a great decrease. No excessive sickness or mortality, however, appears to have resulted from this scarcity in 1907. The death-rate for the whole province was 26·60 per 1000.

Turning now to the chief diseases, we see that cholera accounted for 8378 deaths, showing an increase of 506 over the previous year. The Irrawady Division, as usual, suffered more than any other. Upper Burmah escaped entirely with the exception of an outbreak in the Lower Chindwar which accounted for over 100 deaths. The Sanitary Commissioner shows how the river water is the chief vehicle for the spread of the disease. Thus at Rangoon it was practically confined to dwellers on or by the banks of the river and main creeks not provided with a pipe water-supply or with an efficient conservancy system. A number of samples of river water stored in the dwellings of persons infected with cholera were found to contain vibrios giving many of the reactions typical of the vibrio choleræ, and similar organisms were present in samples of water taken from the streams and creeks in the vicinity. Such water is employed in cook-rooms to wash the food utensils and for other domestic purposes. The cold fresh water tanks were not under suspicion as they were resorted to by a large population of Burmans and others who did not suffer from cholera, and microscopical examination of samples of the water showed it to be free from vibrios. During the last two successive years a row of buildings overhanging the river in the Kamakisit quarter, and occupied by Mahomedan Khalasis employed on river launches and steamers, supplied many cases of cholera, whilst the residents of the adjacent rows of houses a few feet away, nearly all Burmans, escaped infection. The latrines used by the Mahomedans overhang the mud shore, which is washed by each returning tide, and from the water thus polluted the residents of the huts drew their supplies, which were found stored in jars adjacent to their cooking places and drinking water-jars, and either supply was, no doubt, used somewhat indiscriminately by the cooks. In the North Kemmendine quarter of Rangoon the water of a certain well was found to originate cases; its closure put a stop to the disease. The Sanitary Commissioner also thinks that the river water is itself the vehicle for the spread of the cholera poison, as the excreta of 50,000 persons fall into it directly from overhanging latrines or are washed into it by the rising tides or by heavy rain. To remedy these defects an ample supply of fresh water is recommended for all purposes, whilst an efficient system of conservancy must be introduced into the riparian quarters and the shores of the rivers and creeks must be kept free from pollution. Thus the spread of infection will be reduced, although the population afloat will still be a source of danger. Amongst the preventive measures introduced we are glad to notice that facilities for boiling water were adopted, the washing of clothes in the river was prohibited during the cholera season, and the erection of new dwellings close to the banks of the creeks was prevented in accordance with the policy suggested by that energetic officer, Colonel King.

Regarding fevers, we note that there was an increase of 3401 cases over the return for 1906. Enteric fever was found to be more widely distributed than was formerly supposed, the diagnosis having been confirmed by Widal's reaction and by post-mortem examination. Distribution of quinine by tablets, which are much preferred to powders on account of the bitter taste of the latter, takes the first place in the preventive measures against malaria in this province. Other measures are the formation of mosquito brigades, drainage schemes, and the clearing of brushwood in the vicinity of towns. Small-pox occurred in 1908 with less frequency in Lower Burma than in 1907, there being 6371 fewer deaths, whilst in Upper Burma there were, on the contrary, 713 more deaths. A vaccination manual is under preparation for the approval of the Government defining the duties of the district vaccination establishment and enabling thereby its services to be utilised to the fullest advantage. With respect to dysentery and diarrhœa, there was a decrease of 837 deaths on the 1906 return.

As regards plague, an increase of 612 over the mortality of 1906 occurred. This increase was confined, however, to Upper Burma, there being a decrease of 197 in Lower Burma. The Sanitary Commissioner points out tha the disease is really much more prevalent than the return show. Thus there was an enormous unexplained rise in th death-rate at Prome at a time when plague was believed t be in abeyance, and similar occurrences elsewhere lead hi to think that the plague mortality has been under-estimate The measures in force for the limitation of its sprea in already infected areas were surveillance, rat destru tion, cleaning measures, chemical disinfection, earth-oilin evacuation, and inoculation; of these the first was ineffectiv Every measure for the suppression of plague in a defin area must aim at the destruction or exclusion of rats. T effect this all refuse must be removed, the dwellings constantly cleaned, and the quarters for domestic animals mus be separated from those of their owner. Specially traine groups of men must be employed to exterminate the rats.

It has been found by Major Williams and Captain Ba Ket I.M S., special plague medical officer, that infectio usually starts in a neighbouring public bazaar or in th principal stores found in its vicinity. Stables are anothe constant centre, especially pony stables, the wooden floorin of which is so constructed as to leave a secure retreat fo the rats underneath it; in contradistinction, where a masonry pavement was laid down not one rat was observed. The Simpson steam and sulphur fumigator, exhaustively applied, did not have results coming up to expectation, and, moreover, no material for the piping was found capable of resisting the action of the combined steam and sulphur fumes, nor has the asphyxiator machine proved of much service. Major Williams rightly holds that where the wooden floors have been removed to get at the rats it is of chief importance to replace the floors by a masonry plinth or to raise the floors so that inspection and cleansing of the ground underneath can be efficiently carried out. 7,544,645 rats were reported to have been destroyed in 1907. 18,164 persons were inoculated with Haffkine's fluid, of whom only 60 people subsequently contracted the disease, with 43 deaths. Not much benefit accrued from earth-oiling. Chemical pulicides, as a spray, such as izal or cyllin with petrol, are claimed to have germicidal as well as pulicidal qualities, concerning which experiments are being carried out. In conclusion, the prevalence of plague was found during the last six months of 1907 to have been much less than in the corresponding period of previous years in nearly all towns and districts.

The remaining portion of this valuable report contains an account of the Port Health Department, of the civil sanitary work, some remarks on the necessity of model sanitary work, with the various appendices. Last year we dwelt on the extremely able report of 1906 of Colonel King, the Sanitary

Commissioner, and from a consideration of the one for the year 1907 we see that his mantle has fallen on no unworthy shoulders.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary Comitia was held on April 5th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that he had nominated Dr. W. Pasteur as the representative of the College at the 350th anniversary of the foundation of the University of Geneva to be held in July next.

The PRESIDENT expressed his thanks to the College for the expression of sympathy on the death of Lady Douglas Powell, passed at the last Comitia.

The PRESIDENT then delivered his annual address, in which he offered congratulations to those Fellows, Members, and Licentiates of the College who had received Royal honours during the past year. He also referred to the awards of medals, prizes, and scholarships by the College and drew attention to the Harveian oration and the lectures which had been delivered at the College. He mentioned the gifts to the College, particularly that of the late Mr. Charles Coates of Bath who gave £1000 for the purposes of the hospitality of the College. The financial condition of the College was satisfactory. He alluded to the increased number of colonial graduates who had applied to be admitted to the examinations, and also to the action which had been taken to oppose the charter or certain of its clauses which was being asked for by the British Medical Association. The President then proceeded to read obituary notices of those Fellows who had died during the past year:—Dr. C. J. Cullingworth, Dr. Edwin Rickards, Dr. B. L. Abrahams, Dr. Henry Ashby, Sir Thomas Stevenson, Sir Henry A. Pitman, Dr. Charles E. Beevor, Dr. Peter Horrocks, Mr. Charles Coates, and Dr. Arthur Gamgee. He concluded by expressing his thanks to the officers, censors, and Fellows of the College for the services which they had rendered him during his year of office.

The SENIOR CENSOR (Dr. NORMAN MOORE) moved, and the SECOND CENSOR (Dr. F. DE HAVILLAND HALL) seconded, that the President should permit his address to be printed. This was carried and the request was acceded to.

Sir R. Douglas Powell then vacated the chair. A vote of thanks to him for his services during the past year was moved by Sir W. S. CHURCH and seconded by Dr. C. THEODORE WILLIAMS, and carried with acclamation.

The election for President then took place, when Sir R. Douglas Powell was re-elected by a very large majority. The charge and insignia were delivered by the SENIOR CENSOR. The PRESIDENT then gave his faith to the College, and thanked the Fellows for the honour once more conferred upon him.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England, reporting the proceedings of its council on Feb. 11th and April 1st last. 2. From Miss Amy Maxwell, offering through Sir William Allchin for the acceptance of the College a photographic copy of a miniature portrait of her grandfather, Dr. Anthony Todd Thomson, a former Fellow of the College. The gift was accepted and the thanks of the College were ordered to be returned to the donor.

After some discussion the following by-law for the admission of women to the examinations of the College for qualifications was enacted for the first time:—

[illegible]

A communication was received from the Harveian librarian (Dr. J. F. Payne) on a proposed commemoration of the 400th anniversary of the birth of Dr. Caius, formerly President and benefactor of the College. Negotiations were proceeding with Gonville and Caius College, Cambridge, for reprinting some of Caius's works.

A report from the Committee of Management, dated March 9th, was received and adopted. The report recommended that the University of St. Andrews be added to the list of institutions at which the complete curriculum of professional study required for the diplomas of the Royal Colleges may be pursued and whose graduates may be admitted to the final examination of the Examining Board in England, on production of the required certificates of study.

The PRESIDENT then dissolved the Comitia.

THE MEDICAL INSPECTION OF LONDON SCHOOL CHILDREN.

THE London County Council at two recent meetings had under consideration an important report signed by its Education Committee in December last and containing the recommendations of its subcommittee appointed in July, 1907, to inquire into: (1) the existing provision for the medical treatment of the Council's school children; (2) the extent to which this provision could be rendered more available by the action of (*a*) the hospitals, (*b*) the Council; (3) what additional provision, if any, is desirable; and (4) how this provision should be supplied. The Council had also before it a comment by the Finance Committee upon this report, of which we now print a summary together with a short account of the Council's debate upon the matter. The subcommittee who presented the report was constituted as follows:—*Members of the Council or of the Education Committee*—The Chairman of the Education Committee, the Vice-Chairman of the Education Committee, Miss N. Adler, Mr. A. A. Allen, Dr. R. M. Beaton, Mr. S. J. G. Hoare, Mr. E. A. H. Jay, Miss A. Susan Lawrence, the Hon. H. Lygon, Mrs. Wilton Phipps, Dr. A. Salter, Major Skinner, and Mr. Graham Wallas. *Representatives of outside institutions*—Mr. Norman G. Bennett (British Dental Association), Sir Victor Horsley (British Medical Association), Dr. Sidney Phillips (Central Hospital Council for London), Dr. Charles Gray (Charity Organisation Society), the Right Hon. Lord Cheylesmore, C.V.O. (Metropolitan Hospital Sunday Fund), Mr. Douglas Owen (London Hospital), Mr. Robert J. Bland (Royal London Ophthalmic Hospital), and Dr. H. Morley Fletcher (St. Bartholomew's Hospital). This subcommittee held ten meetings, at which the following witnesses were examined:—Mr. Herbert Parsons, Dr. J. H. Sequeira, the late Dr. L. Abrahams, Mr. P. Macleod Yearsley, Mr. Wallis, Mr. Bishop Harman, Miss Wright (head mistress of Shepperton-road L.C.C. school), Miss Foxlee (head mistress of Haseltine-road L.C.C. school, and formerly head mistress of Waterloo-road L.C.C. school), and Miss E. M. Phillips (head mistress of Hanbury-street L.C.C. school), Mr. Warren, and Mr. Hancock Nunn. It also considered a report of the section of the day schools subcommittee on the work of the medical officer, memoranda by Mr. Norman Bennett, Mr. Herbert Parsons, and Mr. Bishop Harman, a memorandum prepared by the British Dental Association, and a report from Dr. G. Cunningham on the working of the Cambridge School Dental Clinic.

The following inquiries were addressed to 50 hospital authorities in a circular letter:—

(i.) What number of children of school age is being treated at the hospitals.

[illegible]

(v.) Whether the hospital authorities are satisfied with what they are able to do in regard to children with tubercular bone diseases.

A further letter was addressed to 198 hospitals, dispensaries, and kindred institutions within the county, asking,

[illegible] under 14 was treated during the years [illegible] the teeth, distinguishing between [illegible] traction of teeth? [illegible] 14 was treated during the years [illegible] the eyes, distinguishing between [illegible] cases? [illegible] the treatment of children under [illegible] of children [illegible] *b*) to use the [illegible] hours for the [illegible]

Council. The summary and recommendations made by the subcommittee in reply to the first three questions submitted for their consideration were as follows:—

1. Such facilities as exist for the medical treatment of school children are provided by hospitals, dispensaries, infirmaries, &c., and the general practitioner.

2. Many of the above-mentioned institutions with their existing accommodation can do no more so far as the treatment of the cases indicated is concerned. Some could do more if assisted from public funds; others could do no more whether assisted or not.

[illegible] ...modation exists to deal wi[illegible] ...reatment. On the other ha[illegible] children a large amount of [illegible] which is inadequate and in[illegible] ...ngworm, favus, suppurating ears and adenoids, debility and tuberculosis are as follows—

(a) Teeth.

(1) That there is a prevalence of dental caries among children attending public elementary schools, and that the existing accommodation in the hospitals and dispensaries, for even simple dental examination and treatment is wholly inadequate. (2) That it is desirable that provision should be made for simple dental treatment of school children. (3) That it is desirable that instruction in the hygiene of the teeth should be given to school children and to their parents or guardians. (4) That it is desirable that the daily use of the tooth-brush by children in their homes be encouraged. (5) That it is desirable that from time to time children be examined as to the cleaning of their teeth.

(b) Vision.

(1) T[illegible] ...ffering from defective vision. (2) Th[illegible] ...ol instruction, and, in many cases, [illegible] affected. (3) That neglect or delay [illegible] ...onic or permanent disability. (4) Th[illegible] ...ases, the existing provisions for their examination and treatment are [illegible] the delay and loss of time suffere[illegible] distance, hospital treatment for th[illegible] in the children not being treated [illegible] modation in the hospitals and dispensaries for such treatment is inadequate. (6) That all cases treated should be re-examined every other year. (7) That additional provision is desirable for the treatment in the vicinity of the school of all children suffering from errors of refraction.

(c) Ringworm.

(1) That, owing to this obnoxio[illegible] children, estimated at 2950 annual[illegible] vented from attending school and [illegible] (2) That the cure of the disease by lotions and ointments is a process occupying many months, or in some cases even several years, the patient being meanwhile prevented from attending an ordinary school and remaining a source of infection. (3) That the disease is now capable of being cured rapidly by x ray treatment, the child ceasing at once to be a source of infection and able to resume school on the re growth of its hair. (4) That, owing to the fact that x ray treatment is provided only at a few hospitals, where its use is greatly in demand for a variety of adult and other diseases, the treatment is available only to a very limited extent for ringworm cases. (5) That the delay and loss of time suffered by parents seeking, often from a distance, treatment for the children affected frequently results in unwillingness to submit the child for treatment, the child meantime remaining a source of infection. (6) That by means of the x ray treatment the disease can be practically stamped out, thus rendering unnecessary the present schools specially maintained for children suffering from it. (7) That provision is desirable for the treatment of the disease by x rays at a fixed centre or centres. (8) That power shall be given to compel the attendance of children for treatment immediately on discovery of the disease.

(d) Favus.

(1) That the present special treatment of cases of favus disease in one special school should be continued.

(e) Suppurating Ears; Adenoids.

(1) That cases of suppurating or discharging ears are greatly prevalent amongst children, about 1 per cent., or 7500 children, being thus afflicted, more especially those in insanitary surroundings. (2) That neglect of the complaint frequently results in deafness or defective hearing, and sometimes in consequence is dangerous to health or even life; in most cases the child being more or less disqualified from profiting by the school instruction. (3) That the cure of such cases involves skilled syringing of the ears daily as well as dressings. (4) That such treatment cannot in most cases be given at the child's home, and cannot be undertaken by the hospitals, even if the parents were able and willing to take the child there for [illegible] desirable for the proper treatment of [illegible] vicinity of the school. (6) That any [illegible] ment other than as above described, [illegible] adenoids calling for operation, should [illegible] treatment.

(f) Debilitated Children.

(1) That a considerable number of children living in insanitary conditions are so debilitated as to be unable fully to profit by instruction in school, or attend without further deterioration. (2) That such children especially succumb to tubercular infection as well as other diseases. (3) That it is desirable that further provision be made of schools on the lines of the existing open-air day schools at which debilitated children could be admitted by the local education authority for short periods.

(g) Tuberculosis.

(1) That tubercular disease with its consequences disqualifies children, if able to attend school, from taking due advantage of school instruction. (2) That many cases discharged after treatment from hospital, and other cases not treated in hospital or convalescent home, require [illegible] care, [illegible] arranged [illegible] earlier stages, and that it is of the first importance that it should be so treated. (4) That children in whom tubercular disease of the bones or joints is detected should be sent to their private practitioner or to hospitals for treatment.

With regard to Question 4, the subcommittee presented a reasoned argument as to whether the requisite additional treatment should be provided by (1) setting up school clinics under the immediate supervision of the local authority, or (2) utilising existing types of institutions, giving, if necessary, financial assistance. It found that the latter course was contemplated by the Act of 1907, and added: Further, the Board of Education Circular, 596, p. 8, draws special attention to the powers referred to in this proviso under the heading "Contributions to Hospitals, Infirmaries, Dispensaries, &c.," and goes on to state, "The Board of Education consider that, before the direct treatment of [illegible] is undertaken by the local education authority, whether by means of a school clinic or by themselves [illegible] and paying for medical treatment, full advantage should be taken of the benefits of such institutions." The Board will be prepared to entertain proposals for contributing to the funds of hospitals, dispensaries, and nursing associations on terms of adequate advantage. Such contributions are specially desirable in the case of eye hospitals and cottage hospitals which are prepared to undertake minor surgical operations. It is permissible to include among the conditions of contribution a provision allocating a [illegible] remuneration to the medical men working for such [illegible] tions. On p. 9 the circular continues: "The establishment of school clinics for purposes of treatment of defects revealed by inspection gives rise on the other hand to questions of considerable difficulty," which are then set out. After further comments the subcommittee made the following recommendations:—

(a) That, as the existing provision of private and hospital [illegible] sufficiently meets the requirements in the case of children [illegible] operative and in-patient treatment (who are thus removed from direct purview of the educational authority), no further steps be [illegible] in respect of this class.

[illegible] additional provision for the medical trea[illegible] has been found desirable, the Council [illegible] types now existing, giving financial help, if necessary, and receiving special facilities in return for any grant of public money, but that in districts where no suitable institution exists, and where [illegible] shall have been found impossible to make th[illegible] extension of existing institutions the Counci[illegible] in default of other means, it shall make the provision itself, and that it be referred to the Education Committee to report further on the matter.

(c) That the report of the Education Committee on the medical treatment of children, and the statements (Nos. 1 (I.-III.)) separately submitted on 30th March, 1909, be placed on sale and circulated in the usual manner.

This report was referred to the Finance Committee of the Council, which at the Council's meeting on March 30th presented its comments upon the proposals of the Education Subcommittee. The Finance Committee referred to the reception by the Prime Minister and Chancellor of the Exchequer of a delegation of local education authorities from England and Wales, to which he held out no hope that any increased grant could be made at present from the Exchequer in connexion with medical treatment. The Finance Committee concluded its remarks with this warning:—

> In connexion with the general question whether the Council should undertake the medical treatment of children it should be borne in mind that the education rate is rising and that it must, under present conditions and in the absence of increased Government grants, continue to rise, this being due amongst other th[illegible] increases in teachers' salaries, the cost of feeding [illegible] new duty imposed on the Council of t[illegible] of all children in elementary schools [illegible] Council is committed. It should als[illegible] being brought to bear upon the Council to increase its expenditure in connexion with education in various other directions, amongst which the question of a complementary superannuation scheme for teachers may be mentioned. The question which naturally arises is whether there is not a limit to the burden which the ratepayer should be called upon to bear in connexion with education, and whether, as between the many objects desirable in themselves which go to make that burden unduly heavy, it will not be necessary for the Council to make a selection.

Mr. JACKSON moved the adoption of the Education Committee's recommendation:—

> That to supply the additional provision for the medical treatment of school children which has been found desirable, the Council should utilise institutions of the types now existing, giving financial help, if necessary, and receiving special facilities in return for any grant of public money, but that in districts where no suitable institution exists,

[illegible] been found impossible [illegible] ion of existing institu- [illegible] lefault of other means, [illegible] o referred to the Educa- [illegible]

Mr. Jackson mentioned that it was hoped shortly to have a conference of hospital chairmen and secretaries to discuss what could be done by the hospitals and what the Council could do to help them. He was bitterly disappointed that the Prime Minister had receiv [illegible] Council's request for increased [illegible] medical treatment, but even [illegible] ance they must make some efforts to deal with the appalling state of affairs which the committee had found to exist. He could not advise the Council to undertake full treatment, important and necessary though it was. Dental treatment was the most expensive, with the exception perhaps [illegible] Council [illegible] ears, ar [illegible] with voluntary institutions which the committee suggested he hoped that dispensaries would not be overlooked. [illegible] etimes been the subjects of unfair [illegible] l should also extend its interest to [illegible] h had done so much for the sick poor.

[illegible] whilst declaring himself in hearty concurrence with the policy of the Education Committee, moved a long amendment which declared that the Council is of opinion that certain diseases of children should be treated, and referred it to the Education Committee to report as to the cost of treating each of the diseases mentioned in its report and as to the steps necessary to be taken to [illegible] visions) Act, 1907, [illegible] medical treatment [illegible] idea was that with the cost of treating each disease ascertained the Council could say which it would undertake. Without going so far as to say they would never treat the children's teeth, he did think they ought to wait until they had power to recover the cost from parents.

The subsequent proceedings were curious in view of Mr. Hayes Fisher's declared sympathy with medical treatment. His seconder, Mr. GRAY, talked the motion out. The debate stood adjourned until the next meeting of the Council.

At the same meeting the modified scheme of medical inspection approved by the Board of Education, to which we referred in THE LANCET of March 27th, was received. Mr. Johnson and Mr. Jephson had amendments on the paper, but they withdrew them after protesting that the scheme was inadequate.

The debate was resumed on April 6th, when it was announced that the Education Committee adopted Mr. Hayes Fisher's amendment.

Dr. SALTER thereupon moved the reference back with instructions *to the committee to submit a detailed scheme for the establishment of school clinics.* He urged that London hospitals were so distributed that they could not provide medical treatment for the children in many districts. The whole weight of medical opinion in London and England, of the dental profession, and of the British Medical Association was unanimously in favour of school clinics.

Mr. BRAY, who seconded, criticised the proposal of the Education Committee to recognise juvenile friendly and other benefit societies. He objected to the teachers and the organisation of the schools being used to canvass on behalf *of these societies and for the ultimate abolition of the* private practitioner.

Mr. C. U. FISHER pointed to the passing of the Education Act of 1870 as the first step in the undermining of parental responsibility. He looked with suspicion on the employment of medical men and dental surgeons by the Council because, although the fees paid might be small at first, they tended to increase.

Mr. ERNEST GRAY, who spoke again on the amendment, took the same line. He seriously distrusted estimates of the cost of medical treatment prepared by the medical profession.

Mr. A. A. ALLEN, M.P., supported clinics because he believed they would be in the long run the cheapest and the most efficient. Mr. Allen put forward an estimate of the cost of medical treatment based on his own calculations. The Council at present engaged medical men for quarter *time—three half-days a week or nine hours—at* £150 a year each. On that basis it would be possible to deal with 6000 to 7000 dental cases per annum and half that number of eye cases in one clinic. If 12 clinics were established, 70,000 to 80,000 dental cases could be treated and about half that number of cases of defective vision. The cost would be about £25,000 per annum. [illegible] to 42. [illegible] lment requiring that a [illegible] providing for medical [illegible] institutions at present in existence and establishing school clinics where other provision is inadequate." Dr. Beaton said a word in defence of dispensaries, which several members had criticised, and, with reference to the amendment, urged that if aid were given to hospitals and school clinics were established as well, it would be possible with the two systems going on side by side to decide which was the better.

This amendment, however, was also defeated, and Mr. Hayes Fisher's proposal was carried. The Education Committee will therefore prepare another report going into the question of cost.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on April 1st, Mr. HENRY MORRIS, the President, being in the chair.

The SECRETARY reported the death of Mr. James Hardie, a past member of the Council, and a vote of condolence with his relatives was passed.

On the recommendation of the Museum Committee it was resolved to request Dr. R. T. Leiper to undertake the revision and renovation of the collection of entozoa.

The Jacksonian prize was awarded to Mr. J. P. Lockhart Mummery for his dissertation on the Pathology and Treatment of those Conditions and Diseases of the Colon which are relievable by Operative Measures. Mr. Mummery was requested to attend the ordinary meeting of the Council on May 13th to receive the Jacksonian prize.

The Council decided that the subject for the Jacksonian prize for the year 1910 should be *Tuberculous Disease of the* [illegible] Organs.

[illegible] *rize was awarded to* Mr. [illegible] his original and other scientific work on dental anatomy, surgery, and pathology.

The best thanks of the Council were given to Dr. Norman Moore for his services as visitor to the examinations of the Egyptian Medical School at Cairo.

The Senate proceeded to the election to the Fellowship of Members of 20 years' standing, and the two following were elected—Sir Shirley Forster Murphy, medical officer of health of the *Administrative County of London*, and Mr. George Dancer Thane, professor of anatomy at University College, London.

Mr. H. H. Clutton was reappointed one of the two representatives of the College on the Senate of the University of London for a further period of four years.

The best thanks of the Council were given to Mr. J. Ward Cousins for his report of the proceedings of the Central Midwives Board, and for his very efficient services as the representative of the College on that Board during the past six years. [illegible] *of the Coll* [illegible] occasioned [illegible] te of [illegible] the celebration of the [illegible]

The PRESIDENT stated that Mr. A. Pearce Gould's period of office on the Court of Examiners would expire on May 12th next, and that the vacancy thus occasioned would be filled up at the ordinary meeting of the Council on May 13th.

Diplomas of Member were conferred upon the following gentlemen who have passed the necessary examinations and have now complied with the by-laws: George Aldon Greaves, M.D., C.M. Queen's University, Kingston, of Queen's University and London Hospital; and Arthur Salusbury MacNalty, B.A., M.B., B.Ch. Oxon, Oxford University and University College Hospital.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 9th, 1831.

ACADEMIE NATIONALE, PARIS.

OBLITERATION OF THE VAGINA BY THE INJECTION OF SULPHURIC ACID TO PRODUCE ABORTION.—CÆSARIAN OPERATION.—DEATH.

THIS singular case is detailed in a letter addressed to M. Guerin, it occurred in a married woman, the mother of four children, and pregnant of a fifth. At the commencement of her pregnancy, she was induced by a female neighbour to inject sulphuric acid into her vagina, as an extremely easy mode of inducing premature labour; dreadful inflammation set in, the parts swelled, great general disturbance ensued, and finally the vagina was so effectually obliterated that she could no longer endure the embraces of her husband; nevertheless, she kept the circumstance a secret till the full term of her gestation was expired. The medical men on examination found that a kind of irregular band surrounded and obstructed the vagina, beyond which, and on the brim of the pelvis, the head of the infant was distinctly felt, pressed forward by the uterine contractions. It was resolved to make an incision through the dense membrane, but when this was done, it was found that it adhered to the bladder, which the incision had completely divided. The delivery was not at all facilitated, and the attendants felt themselves compelled to perform the Cæsarian section. The infant was extracted, dead, apparently for some time, and the mother immediately expired.

BRITISH MEDICAL BENEVOLENT FUND.

AT the March meeting of the committee 23 cases were considered and grants amounting to £185 made to 19 of the applicants. Appended is an abstract of the cases relieved:—

Daughter, aged 45 years, of late M.D. Lond. Underwent a serious operation about a year ago and is unable at present to earn a living. Income only a few shillings a week. Relie[illegible]

Widow, aged [illegible] n a situation as [illegible] ing her husband during the two years illness [illegible]. Voted £10.

[illegible] of L.S.A. No income. Eight children, but only able to give slight help. Proposes to move so as to decrease her rent. Relieved ten times, £115. Voted £5 for moving.

Widow, aged 62 years, of L.F.P.S. Glasg. No income. Four children, but none able to help at pre[illegible]

Widow, aged 38 years, o[illegible] r a few months after marriage [illegible] rs, who can ill afford to help. [illegible] of permanent occupation. One child, aged four years. Voted £5.

Daughter, aged 50 years, of late M.D. Aberd. Has supported herself for many years by giving music lessons, but finds increasing difficulty in obtaining pupils. Is in bad health and ordered to take a rest. Voted £6.

Daughter, aged 44 years, of late L.R.C.P. Edin. Used to be a dressmaker, but employers retired from business and applicant has found it impossible to get regular work since. A little help from a friend and earns as much as possible by sewing. Relieved four times, £40. Voted £6.

Widow, aged 60 years, of L.R.C.S., L.R.C.P. Irel. Lost everything through the failure of a bank, and is now in a very precarious state of health. No income; helped by a sister, who herself has to earn a living. Relieved twice, £24. Voted £12.

Widow, aged 59 years, of L.S.A. Lets lodgings; five children but only able to give very slight help. Relieved seven times, £80. Voted £10.

Widow, aged 51 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided for at husband's death a few years ago. Obtains shelter as a caretaker but receives no remuneration. No children. Relieved five times, £46. Voted £12.

Widow, aged 64 years, of M.D. Glasg. No income and for several years has been practically dependent on this Fund and the Ladies' Working Guild. Relieved nine times, £104. Voted £10.

Widow, aged 50 years, of M.R.C.S. Eng., L.R.C.P. Edin. Kept a boarding house and nursed her husband for several years previous to his death, but is now in such bad health that she is entirely dependent on her friends and a couple of sons who are only just self-supporting. [illegible] Voted £10.

[illegible], of M.R.C.S., L.R.C.P. Has a small annuity, [illegible] that it is insufficient for unavoidable expenses. [illegible] and 12 years. Relieved five times, £72. Voted £12.

Daughter, aged 54 years, of late L.F.P.S. Glasg. Unable to obtain regular employment on account of ill health. Only income £10 a year from the Scottish Indigent Gentlewomen's Fund. Relieved twice, £24. Voted £12.

Widow, aged 48 years, of M.R.C.S., L.S.A. No income, endeavours to support herself by needlework and receives a little help from friends. Two children, aged 22 and 16 years. Relieved six times, £71. Voted £12.

Daughter, aged 52 years, of late M.R.C.S., L.S.A. No income and in very feeble health. Receives a little help from a sister. Relieved 11 times, £125. Voted £12.

Widow, aged 63 years, of M.D. Aberd. No income. Children unable to help. A little assistance from friends. Relieved eight times, £1[illegible] Voted £12.

Daughter, aged 60 years, of late M.R.C.S. Had a post as companion but was obliged to give it up to nurse two sisters who have since died. Hopes to obtain boarders and is made a small allowance by a relative. Relieved twice, £30. Voted £12.

Widow, aged 51 years, of M.D. Edin. No income. Children help as far as possible and applicant earns a little by needlework. Relieved three times, £30. Voted £10.

Mr. W. E. Sargant, St. Bartholomew's Hospital, E.C., is the honorary secretary to the Fund, and Dr. Samuel [illegible] the honorary treasurer.

MEDICINE AND THE LAW.

The Sanitary Oath.

A PRIVATE Member's Bill, having for its object the general introduction of the Scottish form of administering the oath to witnesses and others, has been introduced in the House of Commons, and apparently as it has been read a second time it may in due course become law. It is now open to a person to whom an oath is administered, if he so desires, to swear in the Scottish fashion, and thus to avoid kissing a dirty and possibly dangerous Testament. Under the Oaths Act, 1888, however, which permits this, judges and others before [illegible] oaths are administered to witnesses either do not consider themselves justified in ordering the oath to be taken in a sanitary manner or are indifferent upon the subject, and sometimes they have been inclined to be contemptuous towards witnesses who, if they desire not to kiss the Book are obliged to express their objection to doing so. The [illegible] referred to above does not do away altogether with the [illegible] form by forbidding it and by prescribing a new one in its place, but seeks to enact as follows:—

> Any oath may be taken by uplifted hand in the same form [illegible] manner in which it is usually administered in Scotland, and the [illegible] (unless the person about to take the oath volun[illegible] same in such form and manner with[illegible] that the Court or officer may [illegible] ing the witness, jury, or deponent [illegible] person in the words thereof and obtaining his or their [illegible] ce thereto without requiring the witness, jury, or person [illegible] repeat the words of such oath.

The reason is not plain for making the use of the new form permissive only, in preference to making it obligatory, at any rate in courts of law, unless objected to. In this case commissioners of oaths might have been left to follow the example set, or to continue to give those swearing [illegible] Testaments to kiss, unless they expressed preference for the Scottish form. Why anyone should prefer to kiss a book to abstaining from doing so is not clear, but the new [illegible] seems to assume that some will display this strange taste and there does not seem to be much harm in providing for its gratification. As matters stand it is apparently expected that the clause quoted above will serve the purpose desired and render the Scottish oath more or less universal, with the modification that it may be administered in the [illegible] person. In the new circumstances contemplated the [illegible] of the court will presumably commence his adjuration by saying "Do you swear by Almighty God," and the witness or juror having listened to the statement of that to which he is to bind himself will concur by saying with uplifted hand, "I do" or possibly "I swear." It would have been as clear and more convenient to have printed the [illegible] be used in the Bill instead of referring to the practice in Scotland, but Parliamentary draughtsmen seem to take pleasure in the introduction of references to existing laws and customs wherever they are possible. Allusion has been made so often in THE LANCET to the dangers arising out of kissing the Book that no more need be said here on the subject. It may, however, be useful to remind Members of Parliament who may be indifferent upon the matter, of a fact recently referred to by Mr. F. W. Lowndes, in a paper read by him at the Liverpool Medical Institution. He reminds us that some years ago Lord Collins (then Mr. Justice Henn Collins in two criminal trials heard by him, the one at Liverpool, the other at the Central Criminal Court, found that witnesses who had given evidence were suffering from syphilis, and ordered the Testaments which they had kissed to be at once destroyed. The attention thus called by his lordship to an unclean practice may be found to have contributed to its abolition, but this will have taken a long time to compass. Protests against the old method have been constantly uttered by the medical profession for more than 20 years, and none has been more persevering or more forcible in expressing them than Mr. Lowndes, to whose recent utterance on the subject reference has been made.

Liability of Hospital Governors.

The case of Hillyer *v.* The Governors of St. Bartholomew's Hospital, which came before Mr. Justice Grantham and a special jury last week, was one of a most unusual kind. The facts were briefly these. The plaintiff, a medical man, sought to make the defendants, the Governors of St. Bartholomew's Hospital, [illegible] ducting an operation up[illegible] injury to his arms by b[illegible] Owen, consulting physician of St. George's Hospital, said that he had known the plaintiff for some time. He was a man of remarkable physique. Previously to the operation he was only suffering from sciatica. He examined him after the operation. He was suffering from an injury resembling a burn on the inside of the left arm, with paralysis of that arm, atrophy of the muscles, and intense pain. The injury to the right arm was less serious, but there was reason to fear that the full use of the left arm and hand would never be recovered. One of the most elementary maxims of surgery was that the arms of a patient under an anæsthetic should not be allowed to hang down from the operating table in such a position that anything could press upon them. He saw nothing in the plaintiff to suggest that he was in the habit of taking overdoses of morphine. Malarial fever might create a predisposition to neuritis. Sciatica was a form of neuritis of the sciatic nerve, or the sheath of it, but sciatica would not predispose to neuritis in another part of the body. Neuritis was not a very usual result of a burn. Paralysis produced by pressure would show itself at once. It might last for months. The plaintiff had been for some time in 1904 and 1905 at a mine on the Gold Coast. In 1906 he had whilst in England two sharp attacks of sciatica, and in March, 1907, he went into St. Bartholomew's Hospital. He was examined under an anæsthetic. When he returned to consciousness he found his left arm absolutely paralysed and the movements of his right arm much impaired. He spoke to the warden and house surgeon and they told him that his arms had not been supported when he was under the anæsthetic, and they could not account for the burn on the left arm unless it had come in contact with the hot water apparatus. After some months his right arm got better, but he suffered such intense pain in the left arm and shoulder that he was in bed for about a year, movement being intolerable. The left arm remained atrophied and practically useless and he would never be able to practise again. His lordship said that the plaintiff had not proved a case of negligence, therefore there must be judgment for the defendants. The question of the liability of trustees and governors of public institutions in the case where negligence of the medical men they employ has been demonstrated was therefore not discussed. This point does not appear to have often come up before the high courts of this country for decision. If, therefore, the case should go to appeal, the decision would [illegible] fact that the s[illegible] with whose sa[illegible] not blind us to the other fact that the great charity of St. B[illegible] But apart from [illegible] ubt that the case [illegible] ich remains for settlement.

MEDICAL CHARITIES.—As a result of the recent performances of *The Gondoliers* by members of the Exeter Amateur Operatic Society, the sum of £100 has been handed to the treasurer of the Royal Devon and Exeter Hospital, and £50 have been given to the West of England Eye Infirmary.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Sutton Coldfield.—Dr. A. Bostock Hill advised the closing of four schools in this district during 1908, but he adds that, except in special cases, he is not in favour of this measure, as he is satisfied that very frequently better results in the public interest can be brought about by the exclusion of definite or suspected cases. There is no doubt that no hard-and-fast rule can be laid down and that the question of school closure has to be determined after a careful consideration of all the circumstances. In a rural district, for instance, it may suffice to exclude the children from one hamlet or village or to close one department only of the school. The mistake which has been frequently made in the past is that sufficient intelligence has not been exercised in the matter, the occurrence of a few cases of infectious diseases having led forthwith to school closure. Alluding to the subject of vaccination Dr. Hill pays a tribute to the work of the vaccination officer who has succeeded in getting 324 cases out of 404 births vaccinated. But 28 parents applied for and received exemption certificates, as compared with eight in the previous year. As Dr. Hill points out, if this exemption process goes on not only will there be many more people unprotected against small-pox but the corporation will have to provide more money for isolation and treatment. This is the unfair side of this exemption business—i.e., that those who have obeyed the law and protected themselves against the disease have to pay rates for the isolation and treatment of the "conscientious" abstainers. It would be more in keeping with equity were those who were successfully vaccinated and revaccinated exempted from any payment of rates relative to a small-pox hospital. There would then be less objection to allowing the ignorant to go as they please in this matter. We want in this country a little of the backbone of the German people who have practically banished both small-pox and small-pox hospitals from their midst.

Reigate Rural District.—Dr. Arthur E. Porter has written a good report upon this district and he is evidently alive to certain matters which are not always called attention to in reports on rural districts. The subsoil in the northern portion of this district is chalk, and the medical officer of health states that a method of sewage disposal which is finding favour with property owners is to connect the interior of the cesspool with the chalk. By this is apparently meant that the cesspool is not rendered impervious or, if it is so rendered, an early opportunity is taken of rendering it pervious. As Dr. Porter observes, the arrangement is convenient but it may provide epidemics of water-borne enteric fever for subsequent generations, and he refers to a recent report of a Local Government Board inspector relative to the abandonment of chalk wells supplying what he terms a "certain East Anglian town." We have been wondering whether Cambridge is in East Anglia. Part of the Reigate district drains eventually in the Thames and the Londoner reads with pleasure of the activity of the Thames Conservancy in the matter of controlling pollution even at this distance from the intakes of the London water-supply. The immunity of London from water-borne epidemics is, having regard to the large number of sewage effluents which enter the Thames, a testimony to two things—the filtration of the Metropolitan Water Board and the purifying forces of nature. In the Reigate rural district considerable vigilance appears to be exercised over the local slaughter-houses, and Dr. Porter reports that the sanitary inspector during a house-to-house inspection of one of the parishes discovered an unregistered slaughter-house which had been in use for about 13 years. We imagine that house-to-house inspections in other rural districts might lead to similar discoveries, as well as to the detection of numerous cowsheds and dairies which have never been registered. The district council in question has adopted certain sections of the Public Health Acts (Amendment) Act, 1890, and new slaughter-houses are now only granted short terminable licences—an example which might be well followed by other rural districts.

St. Annes-on-the-Sea Urban District.—During July of last year there was in this district an outbreak of food poisoning which was attributed to the consumption of potted meat and pork pies which had been procured from a local confectioner, and the bacillus enteritidis of Gaertner was discovered in the foods. Some 80 persons were attacked, the more severe cases [illegible] nal pain, vomiting, diarrhœa, and collap[illegible] deaths. It is not quite clear how the food became affected, but possibly the assistants at this shop were first attacked by the malady and this may have infected the food. Dr. F. Booth, the medical officer of health, has drawn up some regulations for food purveyors, and doubtless such purveyors will now be kept under observation. Three cases of enteric fever were attributed to shellfish, but the dates of consumption are not furnished and the source of the shellfish is not stated. One case is attributed to defective drains. A qualified veterinary inspector was appointed last year, and one of his duties is to examine all the milch cows in the district every three months.

Plympton St. Mary Rural District.—Mr. S. Noy Scott, in referring to the subject of the medical inspection of school children, expresses regret that the county council of Devon did not appoint as school officers such medical officers of health as were willing to undertake the work. He thinks that such a procedure would have been a great step forward, as it would have prepared the way for the appointment of whole-time medical officers of health who would be independent of private medical practice or local prejudice. He regards the present position in the county of Devon as an anomalous one because he is compelled by the Local Government Board to report on, and to be to some extent responsible for, the sanitary condition of the schools; and, while he is the only legally qualified officer who can advise the district council to close the schools, there is an officer appointed by the county council to inspect the scholars over whom he has no authority.

Thingoe Rural District.—Dr. Charles Scott Kilner has instituted a house-to-house inspection of this district, a course which should prove helpful not only as regards the private houses of the poorer classes but as a means of ascertaining the presence of unregistered slaughter-houses and cowsheds. Although these house-to-house inspections in rural districts call for the exercise of great tact and discretion they cannot fail to be helpful both to the officers and to the district council, and we are glad to see that they are now becoming much more general in rural districts than was the case formerly.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon E. R. D. Fasken to the *Terrible* and for Division of Special Service Vessels, Portsmouth.

ARMY MEDICAL SERVICE.

Colonel Jules I. Routh, half-pay list, is placed on retired pay (dated March 29th, 1909).

ROYAL ARMY MEDICAL CORPS.

Captain W. F. Tyndale, C.M.G., has been posted to the Southern Command.

TERRITORIAL FORCE.

Yeomanry.

Warwickshire: Surgeon-Major Roger Bullock is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated March 31st, 1908).

Royal Army Medical Corps.

1st West Lancashire Field Ambulance: Captain Archibald G. Gullan to be Major (dated Dec. 19th, 1908).

1st Northumbrian Field Ambulance: Arthur Gibson Dunn to be Lieutenant (dated Oct. 21st, 1908).

3rd Wessex Field Ambulance: Lieutenant Frederick Ernest Stokes, from the Royal Army Medical Corps, Territorial Force, to be Lieutenant (dated May 19th, 1908).

Lieutenant-Colonel John M. Harper is granted the honorary rank of Surgeon-Colonel (dated March 31st, 1908).

For attachment to Units other than Medical Units.—Arthur Roberts (late Lieutenant, Berkshire Imperial Yeomanry), to be Captain, with seniority as from Feb. 8th, 1905 (dated Oct. 1st, 1908). Harry Bird Sproat to be Lieutenant (dated Jan. 27th, 1909). Surgeon-Captain John Griffiths, from the [illegible] shire Battalion, The South Wales Borderers, to be [illegible] March 1st, 1909).

Unattached List for the Territorial Force.—The undermentioned officer, from the 1st Gloucestershire Royal Engineers (Volunteers), is [illegible] and precedence as in the Volunteer [illegible] 1908):—Surgeon-Major William Cox.

VOLUNTEER CORPS.

Royal Engineers (Volunteers): The Tay Division Submarine Miners: The resignations of Surgeon-Major George Owen Carr Mackness, Quartermaster and Honorary Captain John Henry Luis, and Acting Chaplain the Reverend Harcourt Morton Davidson bear date March 31st, 1908, and not as stated in the *London Gazette* of Nov. 1st, 1907.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force who have been duly recommended for the same under the terms of the Royal Warrant (dated August 17th, 1908):—

Northern Command.

Infantry: 5th Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Major Edmund Vaudrey.

Royal Army Medical Corps: Major Andrew Paige Arnold.

Scottish Command.

Yeomanry: Ayrshire (Earl of Carrick's Own): Surgeon-Lieutenant-Colonel William John Naismith, D.S.O.

Royal Army Medical Corps: Lieutenant-Colonel Thomas Finlayson Dewar.

Southern Command.

Yeomanry: Gloucestershire (Royal Gloucestershire Hussars): [illegible] bert Bramwell. Warwickshire: Surgeon-M[illegible].

Royal Army Medical Corps; Captain Cecil Aloysius Corke.

Western Command.

Yeomanry: Shropshire: Surgeon-Lieutenant-Colonel John Daniel Lloyd.

Infantry: 4th Battalion, The Welsh Regiment: Surgeon-Major Evan Evans.

Royal Army Medical Corps: Major Ernest Wykeham Barnes, Major John William Ellis, and Major Alfred Rees.

TERRITORIAL MEDICAL UNITS.

The following units have been reported as having attested at least 30 per cent. of the establishment authorised, and have received the recognition of the Army Council:—Field Ambulance, 3rd Northern General Hospital, 3rd Southern General Hospital, 3rd Western General Hospital, 1st Northern General Hospital, and the 3rd London General Hospital.

TERRITORIAL FORCE MEDICAL TRAINING ORDERS.

While complimenting medical officers on the arrangements made for the Territorial troops encamped last year, the Army Council has intimated that for the future great attention must be directed to sanitary instruction and water duties. Before going to camp progressive training in all duties is to be very thorough, including mounted work and the study of ground and of danger zones, the collection of wounded, and tactical formations. General hospitals are not to attend camp this year.

The captains' course at the Royal Army Medical College has recently been extended from six to nine months.

"Audi alteram partem."

MOSQUITOES AND MALARIA: A CAMPAIGN THAT FAILED.

To the Editor of THE LANCET.

SIR,—Neither the cause of sanitation nor that of truth is likely to be advanced by the article of this name published in the current issue of THE LANCET by "A Special Correspondent." I have only just seen the article, but fear that I must write at once, in the interests of both, to contradict almost every statement made in it.

The article is merely a *réchauffé* of a paper by Major S. P. James, I.M.S., read at the Bombay Medical Congress last February, but the writer of it omits to mention that in the discussion which followed Surgeon-General H. Hamilton, C.B., promptl the accuracy of I the Congress Lieutenant-Colonel H. D. Rowan, R.A.M.C., who was principal medical officer for some years at Mian Mir, and Colonel H. J. Waller Barrow, who now holds that office, have written to the Allahabad *Pioneer* and the Lahore *Civil and Military Gazette* to the same effect. I regret that I have no copy of Surgeon-General Hamilton's remarks, but I enclose the letters of Lieutenant-Colonel Rowan and Colonel Waller Barrow, and will be very glad if you, Sir, can find space to lay before your readers the sense of what they say. I may add that Colonel J. Shearer, C.B., I.M.S., principal medical officer Dajirat and Bannu Brigades, inspected Mian Mir after the Congress, and that he and Colonel R. H. Forman, R.A.M.C., principal medical officer Bombay, have furnished me with many facts which, together with those of the officers previously referred to, show that Major James's conclusions (as might be surmised by any careful critic of his paper) are completely groundless. The salient points are that the cantonment was never cleared to anything approaching the extent he pretends; that, in fact, shortly before his arrival it had been flooded for weeks by an exceptionally heavy rainfall; that an epidemic of malaria was raging all over the surrounding country; that some of the children examined by him had come to the station only a few months previously; that there is no guarantee that many of the other persons examined by him had not been infected elsewhere (the population being a military and a changing one); that he omits to mention these vital points; and that the statistics furnished by him are quite unreliable.

The writer of your article is scarcely accurate when he describes Major S. P. James and Captain S. R. Christophers as being at the time when they commenced their fiasco at Mian Mir in 1901 "two experts in the subject of malaria prevention." They were then young men who had not long been studying malaria, and I have never heard of any previous practical anti-malaria work done by them—a very different thing. Their first reports were exhaustively criticised by Colonel G. M. Giles, Captain E. P. Sewell, and myself (see *British Medical Journal*, Sept. 17th, 1904), and to these criticisms they did not reply. The more thorough work commenced by General Kitchener in 1904-05 was advised, not by them, but by Surgeon-General Hamilton and Colonel Scott Reid, I.M.S., and Major James now attempts to justify his previous failure by showing that these subsequent measures were as fruitless as his own.

To support this attitude better he states at the end of his paper that success in such operations elsewhere "has been reported on evidence that will not bear criticism and is often ridiculous." F

he referred to

Sir George Cl

and President of the Congress, to ask Prince d'Arenberg, President of the Suez Canal Company, for a full official statement of the results there; and your readers should know that Prince d'Arenberg informs me not only that he will give such particulars (which I hope may satisfy even Indian sceptics) but that he will be glad to accept a commission of inquiry at Ismailia at the most unhealthy time of the year to verify those results

It is surprising that the Sanitary Commissioner with the Government of India should not already have taken the trouble to make such an inquiry. Instead of that the Mian Mir affair *has been allowed to damp anti-malaria work in* India for five years. I have therefore suggested that the Government of India should make an impartial inquiry into the latter campaign also. It is time that the authorities obtain clear ideas on these subjects.

I must point out in conclusion that Major James's paper tends to throw as much discredit on quinine prophylaxis as on mosquito reduction. I am, Sir, yours faithfully,

University of Liverpool, April 4th, 1909. RONALD ROSS.

⁂ We have received from Professor Ronald Ross extracts from the Allahabad *Pioneer* dated March 12th and March 13th, containing letters from Colonel Waller Barrow and Lieutenant-Colonel H. D. Rowan respectively. We do not think we can attempt to summarise these communications—presumably their authors have made them as brief as they know how; but Professor Ross is right in saying that both officers regret Major James's attitude and dispute his conclusions.—ED. L.

McBURNEY'S METHOD OF CONTROLLING HÆMORRHAGE DURING DISARTICULATION AT THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—I can cordially endorse all that has been said in your issue of THE LANCET of April 3rd regarding the control of hæmorrhage during disarticulation at the hip-joint by intraperitoneal compression of the common iliac artery. Some years ago it struck me that the method suggested by McBurney was a most excellent one, and in a case of sarcoma of the femur I employed it with complete success. In the *Scottish Medical and Surgical Journal* for 1902 I gave a brief outline of this case and drew the attention of the profession to the value of the procedure. I have employed it since and feel sure from my experience of it that intraperitoneal compression of the common iliac artery in disarticulation at the hip has only to be known to be widely employed. In my cases no preliminary ligature of the femoral artery and vein was performed. This is a step which does not seem to me to be necessary. I am, Sir, yours faithfully,

JOHN MARNOCH, M.A., M.B., C.M. Aberd.

Aberdeen, April 3rd, 1909.

SPONTANEOUS CURE OF THORACIC ANEURYSM.

To the Editor of THE LANCET.

SIR,—Sir Thomas Oliver describes a case of spontaneous cure of thoracic aneurysm in THE LANCET of April 3rd, p. 971, and refers to its rarity. It may be interesting to him and others to hear of another case. I saw one when I was resident medical officer to the Royal United Hospital, Bath, in 1880. A woman was admitted with *inspiratory dyspnœa unassociated with* any alteration of the voice, and paralysis of the arytænoidæus posticus was diagnosed. There was no history of trouble in the chest and no physical signs pointing to aneurysm or intra-thoracic growth were present. Her death occurred a few days after admission, and at the post-mortem examination we were much surprised to find a perfectly cured aneurysm of the transverse portion of the arch of the aorta; the specimen was placed in the hospital museum, that splendid creation of Mr. Gore, and is probably there now. The case was never reported.

These cases are not only interesting as curiosities but have a great value as showing the possibility of cure of aneurysm of the arch of the aorta. When such cases come under our care we are apt to feel hopeless and almost helpless, but a cure is possible, and it is suggestive that in the case above mentioned the patient had not been laid up in bed—in fact, *had not desisted from* her usual work. In Sir Thomas Oliver's case the man had *only rested* for a few weeks at a time, and the other patient quoted, who lived for as long as 12 years, undertook really violent exercise, all of which rather suggests that our present method of treatment by complete rest in bed may possibly be wrong. Has anyone ever seen a cure from such treatment?

I am, Sir, yours faithfully,

REGINALD PRATT, M.D. Lond., M.R.C.P. Lond.

Leicester, April 5th, 1909.

THE CLINICAL VALUE OF HÆMOMANOMETER OBSERVATIONS.

To the Editor of THE LANCET.

SIR,—Dr. William Russell has not yet grasped the fact that the venous *blood pressure cannot* exceed the arterial, and does not know that the venous pressures which *he quotes* from Professor Starling are measured in millimetres of salt solution, while the arterial pressures are measured in millimetres of mercury and must be multiplied by 13 to compare with the venous pressures. It is useless for me to continue a discussion with him.

Dr. Oliver Williamson's records are an earnest attempt at furthering exact knowledge. I cannot accept his readings of leg and arm pressures unless made simultaneously, because it is just these cases of high pressure where there may come in effects of pain and discomfort from the armlets and effects of blocking part of the circulation. At present the question stands as one of disagreement between observers and can only be settled by extended inquiry. I shall be glad to measure with Dr. Williamson some of his cases and be convinced by him if he can convince me. I have worked too long at research to be carried away by preconceptions, and care for nought but the arrival at the truth on this matter. The fact that in the dog the systolic pressure wave is found by the Hürthle spring manometer to be higher in the femoral than in the carotid must not be lost sight of. The explanation of this which has been given is that the crest of a reflected wave is piled on top of the primary wave in the femoral. It is possible that this may occur in man, and perhaps particularly in high-pressure cases, supposing, of course, that it is not due to some undetected instrumental error. I consider, therefore, that the comparison of the column of blood (separating the two points of measurement) with the difference of the measurements a surer test than the equality of leg and arm measurements taken in the horizontal posture. I am, Sir, yours faithfully,

Loughton, Essex, April 5th, 1909. LEONARD HILL.

THE PROXIMATE FACTOR OF DELIRIUM TREMENS.

To the Editor of THE LANCET.

SIR,—In your accurate abstract of the third annual report of the Norwood Sanatorium (March 27th, p. 956), you refer to the fact that less than ½ per cent. of the 63,000 persons sent to prison for drunkenness developed delirium tremens, although in all sudden and complete withdrawal of alcohol was practised (Medical Section of Prison Statistics for 1906). You advance these statistics as an argument against the view that delirium tremens depends proximately upon a sudden fall in the amount of alcohol circulating within the system. I would submit, however, that if looked at just below the surface the figures quoted constitute evidence favourable rather than hostile to the above view.

There is a general agreement that delirium tremens is a complication which mainly, if not solely, affects the *chronic alcoholic* as distinguished from the dipsomaniac and the numerous varieties of impulsive drunkards; it is especially liable to arise in those who habitually absorb large quantities of alcohol without becoming intoxicated—at any rate, frankly intoxicated. In other words, the liability to delirium tremens is *directly* as the tolerance of alcohol which has been acquired. On the other hand, it will hardly be disputed that the liability to fall into the hands of the police for alcoholism is *inversely* as the acquired tolerance of alcohol. These propositions being conceded, a low delirium tremens rate in police cases is to be anticipated, nor does ½ per cent. seem unduly low.

It is admitted that in the great majority of cases of alcoholism, even chronic alcoholism, alcohol may be withdrawn suddenly and completely without any serious complication arising. That, however, is beside the mark. But what is to the point is the fact that when delirium tremens does arise it is always—without any exception in my experience—in circumstances which involve a large and sudden fall in the amount of alcohol in the system. The circumstances are, of course, various. The withdrawal, or comparative withdrawal, may depend upon medical treatment, as in most of the cases which occurred at the Norwood Sanatorium; or it may even be the result of a sudden effort of will on the part of the inebriate himself. I know of several examples. It may, of course, depend upon inaccessibility, as when a chronic alcoholic meets with an accident or contracts an acute illness necessitating admission to hospital. But in those cases of which it is said that the patient drank himself into delirium tremens—cases in which the drinking of alcohol continued with little interruption up to the point at which the actual delirium commenced—it will usually be found on close inquiry that the determining factor was gastric catarrh with inability to retain, and consequently to absorb, even small quantities of alcohol.

I am, Sir, yours faithfully,
FRANCIS HARE,
March 31st, 1909. Medical Superintendent, Norwood Sanatorium.

CONVENTION OF THE AMERICAN SOCIETY FOR THE STUDY OF ALCOHOL AND DRUG NARCOTICS,

HELD AT WASHINGTON, D.C., U.S.A., ON MARCH 17TH, 18TH, AND 19TH.

(FROM A SPECIAL CORRESPONDENT.)

(Concluded from p. 1012.)

The Alcohol Question in the United States.

Dr. GORDON (Philadelphia), who discussed legal responsibility in acute and chronic alcoholism, held that in chronic alcoholism responsibility is limited because of the diminution in the power of discrimination in the subject. Dipsomaniacs were entirely irresponsible. In this respect the legal test of "right and wrong" was inadequate and must give place to the medical view of anti-social acts, which asks whether the patient can really appreciate their consequences.

Dr. WILLIAMS (Washington) pointed out the evil consequences of removing from a psychopath or defective, whose very nature made him less capable of clear judgment of social relationships, the deterrent of legal punishment.

Dr. MASON agreed with Dr. Williams, and pointed out that whereas crimes of violence were increasing, more particularly in France and America, the inevitability of punishment following crime acted in Great Britain as the most powerful counter-suggestion to the sensationalism of the modern press

Dr. ROSENWASSER declared that periodic dipsomaniacs were in reality epileptic, and were therefore without responsibility. He thought that every accused person should be examined by a medical commission before appearing in court. He believed that 90 per cent. of the defectives who composed the majority of criminals were better off in jail than out.

Dr. MASON discussed very fully the urgent need of legislation for inebriates, and outlined an ideal scheme for dealing with inebriates and mental and moral degenerates as embodied in Bills at present before the Legislature and municipal councils of New York and Brooklyn.

Dr. MACDONALD (Washington) urged the importance of accurate anthropometric data.

Dr. WILLIAMS analysed the psychological bases of inebriety, their etiological and sociological factors, and the remedies for these. He classified inebriates into: 1 Suggestible individuals who were not truly inebriates until the occurrence of tissue degeneration from prolonged drinking; until this happened they were easily curable. 2 Individuals whose suggestibility had arisen by the perpetuation of the impulsiveness of the child from lack of ethical training. 3. The psychasthenically constituted, in whom the feeling of longing had turned towards satisfaction by a narcotic. By difference of environment it might have turned towards mysticism or fetichism. Whatever happened was a habit-reflex, which should have been prevented in youth The remedy was the teaching of mothers to form healthy emotional habits in their children.

Dr. QUACKENBOSS (New York) described the psychical therapeutics of inebriety as employed by him. The cure was performed by suggestion.

Dr. HUGHES (St. Louis) spoke of the neuropathic entailments following the use of alcohol, and said that as softness was a property of living cells, to maintain this the due content of water was required, of which alcohol robbed them, causing induration.

In discussing the paper, Dr. WILLIAMS pointed out that the French psychiatrists did not believe that the alcoholic psychoses were due to the direct effect of alcohol on the brain.

Dr. BERKLEY described lesions in the central nervous system which he had produced experimentally by giving alcohol to rabbits. He gave it in small doses until tolerance appeared, and then increased it until death occurred.

Dr. MASON extolled the value of such research work, and said that he proposed to provide a fund for an annual oration to the public in several large cities in order to commemorate the pioneer work of his father in placing before the public scientific facts about the deleterious action of alcohol. A leading authority would be selected each year to present to the laity the most recent work as it was completed.

Dr. WINFIELD HALL (Chicago) described his experiments upon the action of alcohol, tea, and other common poisons on tissue capacity. Against the argument that because alcohol was found by analysis in human muscle it was therefore a legitimate food, Dr. Hall quoted the experiments of Magnan, who showed that by placing muscle in 1 per cent. sodium fluoride it broke down by stages into (1) acetone, (2) acetic acid, carbon dioxide and water, (3) alcohol, carbon dioxide and water, and (4) entirely into carbon dioxide and water. The alcohol was therefore a mid-product of katabolism and it was as false to infer from this that it was a food proper to ingest as to infer the same thing of uric acid or acetone itself; all were waste products.

Dr. SPRATLING (Baltimore), in speaking of alcohol as a cause of epilepsy, from his ten years' experience in the great colony at Sonyea, New York, declared that he had studied about 1500 epileptics and could therefore speak from his own experience. He was convinced that chronic alcoholism in the parent was a fertile cause of epilepsy in the child.

Dr. CROTHERS, in discussing the paper, emphasised the need of more accurate statistics, pointing out that consideration for the family generally prevented the physician from accurately registering the alcoholic etiology.

Dr. WEBSTER (Chicago), President of the Illinois Board of Health, believed that the relation of alcohol to public health made it the most vital and baffling obstacle to the progress of man. It was as much a medical problem as that of tuberculosis, and should be let alone by fanatics and studied by biologists as a part of the reaction of man to environment. The sooner the researches of physiologists were applied in practice the more chance would there be of diminishing the enormous expenditure caused by alcohol; e g., 50 per cent. [illegible] the police arose out [illegible] the 20 per cent. of [illegible] und that the cost to municipalities was 12 million dollars per annum to dispose of preventable nuisances due to alcohol. This did not take into account loss of time and losses by premature death. Estimating the value of a life at 8000 dollars, Fisher had estimated at one billion four million dollars the loss to the United States per annum by deaths from alcohol, making a total estimated loss of two billions one hundred and forty-two million dollars. This takes no account of the fallaciousness of statistics due to concealment by family and physician, who would generally certify an alcoholic gastritis or nephritis as merely "chronic." In Switzerland and Sweden, and to a less degree in France, statistics were more reliable on account of the guarantee of medical secrecy. Dr. Webster agreed with the pronunciamento of the International Congress of 1905 upon tuberculosis, held at Paris, that to "effectively fight the great white plague it is essential to counteract the influence on the public health of taking alcohol." The medical profession should lead the way in this and avail themselves of all the help they could from such laymen as economists, sociologists, and the clergy. The need for this was apparent when statistics were studied. For whereas in 1900 the consumption of alcohol was 17½ gallons per head it had now reached the amount of 23 gallons per head per annum.

At the conclusion of the papers it was resolved to continue the semi-annual meeting and to convene it again at Washington next year. The annual meeting is always held in conjunction with that of the American Medical Association; but the time for communications and discussions is much curtailed by the section meetings. This meeting, which was supplemented by several addresses by members in the churches of Washington, proved most successful.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

THE Bristol University Bill has been read a second time before the House of Lords. On March 25th a meeting was held at University College to discuss the advisability of forming an Association of the Alumni of the University of Bristol. The matter has already been considered informally by members of the College staff, and on the above date their suggestions were submitted to the meeting. After a brief discussion, in which the advantages derived from the existence of such associations at the Universities of Toronto and Liverpool were dwelt upon, the meeting proceeded to elect a committee to draw up rules and regulations, which will later be submitted to as representative a meeting of alumni as possible.—The claims of classical education were urged in an interesting lecture on "The Power of Antiquity," delivered at University College on March 22nd, by Professor R. S. Conway. He showed that it is a mistake to suppose that there is no room for "idealistic" or classical as opposed to "utilitarian" or technical study in the modern university, and pleaded for the establishment of a strong school of classics in the coming University of Bristol.

The Barnstaple Rural District Council and the Local Government Board.

The Barnstaple rural district council has had friction with the Local Government Board for some time past over the question of the sanitary inspection of the district, and at its meeting held on March 19th a letter was read from the Local Government Board informing the council that if it still declined to appoint two inspectors of nuisances instead of one no part of the salary of the present officer would be repaid them from the county fund. The members of the district council, after some discussion, decided to inform the Board that they did not consider two inspectors necessary. It is to be hoped that the council will reconsider its decision, for it seems impossible for one sanitary inspector to do the work of such a large area as that covered by the Barnstaple rural district council.

The Gloucestershire Infirmary and Eye Institution.

The annual meeting of the governors of the Gloucestershire Infirmary and Eye Institution was held on March 25th. The chairman (Colonel Curtis Hayward), in submitting the annual report and accounts for 1908, said that there had been increases in the number of in- and out-patients, and the cost per bed was £80, as compared with £57 7*s.* 10*d.* 20 years ago. Against an increase of £527 in the expenditure was a decline of £493 in income, and there was a deficit on the year of £1153. The committee does not think it should encroach on capital to defray current expenditure, and it states that it must either have increased financial support or reduce the work of the institution.

The Royal Hospital for Sick Children and Women, Bristol.

The annual meeting of the subscribers of this institution was held on March 29th under the presidency of the Lord Mayor. The medical report stated that during 1908 the in-patients numbered 818 (751 children and 67 women), compared with 785 (727 children and 58 women) in 1907. 3610 children and 1541 women were treated in the out-patient department, as against 3276 children and 1456 women in the previous year. The financial statement was satisfactory, and showed that as a result of a special appeal for increased subscriptions £5386 had been raised. The committee has consequently been able to discharge the adverse balance of £3998 remaining at the close of 1908, and also to defray the cost and equipment of the cottage required for the accommodation of special scarlet fever cases, and the sum of £639 has been carried forward as a small nucleus of a fund for new buildings for the out-patient department.

Hospital Sunday Fund at Bristol.

Up to April 2nd the collections in aid of the Lord Mayor of Bristol's Hospital Sunday Fund were £1853. Last year £1859 were received, and as there are still some collections to come in it is evident that the total of that year will be exceeded.

The Health of Torquay.

Dr. T. Dunlop, the medical officer of health of Torquay, in his annual report for 1908, which has just been issued, states that during the year the birth-rate was 15·4 per 1000. The death-rate was 17 per 1000, but deducting the deaths of visitors the rate was 15·7. Dr. Dunlop says that after many years of almost complete immunity from diphtheria, the borough suffered severely from it, there being 99 cases with 12 deaths. There were 114 cases of scarlet fever, but no case ended fatally. 16 cases of enteric fever were notified, with four deaths; in two instances there was distinct evidence of eating sewage-polluted shell-fish 74 deaths were due to phthisis, of which 17 were in visitors. 69 deaths occurred from cancer. The zymotic death-rate was 1·2 per 1000, against 0·73 in 1907.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

THE executive committee of the Birmingham Hospital Saturday Fund is to be congratulated upon the report it was able to present at the annual meeting. In spite of bad times the places left vacant by the falling out of firms which had previously contributed were more than filled by new contributors, and the total collection reached the record sum of £20,516 13*s.* 1*d.*, or over £520 more than in the previous year. This is an extremely satisfactory result; it is equally satisfactory to note that the expenses of the Fund only amounted to 4·8 per cent., therefore they compare very favourably with those of other large towns. This has always been the case, and Sir Halliwell Rogers, in seconding the motion that the report should be adopted, stated that since the inception of the Fund in 1873 the total amount collected was £400,000 and the expenses for the whole period under £20,000, that is, under 5 per cent. The Fund not only contributes considerable sums to the hospitals of the city but also supports three convalescent homes, one for men, one for women, and one for children, at which during the past year 3072 patients were received. It has been suggested that the Fund should give help to the new provident dispensary scheme.

The Birmingham Lying-in Charity.

The governors of the Birmingham Lying-in Charity are making an urgent appeal for increased support. The charity is doing excellent work both in treating necessitous and deserving cases and in training midwives. The staff of the Maternity Hospital has been increased, the work done has been extended, and the training of pupils has been so successful that 32 out of a total of 34 passed the examination of the Central Midwives Board. The subscription list has been considerably increased, but a deficit of £500 18*s.* 10*d.* on the last year's work and an overdrawn bank account of £1502 14*s.* 4*d.* show that it must be still further augmented if the work of the charity is to be continued on a proper basis. Even if other appeals do not for a time receive adequate support this should not be allowed to fail, for it is a cause to which no humane person can raise the least objection and a charity which helps urgent necessity.

The Amalgamation of Societies for the Relief of Cripples.

The existence of two societies for the relief of cripples has apparently been detrimental to both, and it has therefore been wisely decided that the Crippled Children's Union and the Adult Cripples' Guild shall be amalgamated. The Crippled Children's Union possesses an income of about £1200 a year and a house and grounds, recently given to it by Mr. George Cadbury, upon which it has spent some £3000. At present the house is unfurnished, but the union of the two societies will enable the surplus money of the Adult Cripples' Guild to be utilised for the provision of furniture. In a short time the new property of the combined societies will be ready for occupation.

Medical Inspection in Warwickshire.

In Dr. A. Bostock Hill's report of the results of medical inspection in Warwickshire during the past year a few interesting points stand out. There are 257 schools in the county, but of these only 96 were visited by the assistant medical officers, who report that in 75 of the 96 the arrangements are good, while there are only a few schools in which the general arrangements must be specified as bad or very bad. On the other hand, it is stated that the great majority of schools of the county are not cleaned so frequently as they ought to be. The number of children examined was 3175, and of these over 40 per cent. were suffering from defects necessitating advice. In spite of the fact that, so far as teeth were concerned, instructions were given not to report children who had less than four teeth affected, 17·6 per cent. of the children were reported under the head of defective teeth, that is, 17·6 per cent. had four or more teeth defective, and it is probable, therefore, that the total of defective teeth would not be much less than 83 per cent., which is the average for 10,000 children spread over a large area. So far as Warwickshire is concerned, however, there is a considerable difference between the northern and southern areas, defects being more common in the south than the north. If this disproportion is still found to exist when the examination is completed, a solution of its causation should prove interesting. The other points of the report do not differ in any essential respect from those of reports from other districts.

The Walsall and District Hospital.

At the annual meeting of the general committee of the Walsall and District Hospital the chairman stated that the extensive alterations and additions which had been in progress during the last two years were now completed, placing the institution in a good condition and bringing it fairly well up to date. He expressed the hope that during the present year it would be possible to keep the expenditure within the income, but he drew attention to the existing debt and pointed out that it would be necessary to develop their resources so that the two wards which had been closed might be reopened as soon as possible.

April 5th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Minimising Abuses.

THE eightieth annual meeting of the supporters of the Manchester Children's Hospital was held on March 25th. The report spoke of the greatly increasing pressure on the time of the staff and the accommodation of the building, matters "claiming serious attention." It is well that this question of obtaining hospital medical treatment by all sorts of people, many well-to-do, others poor, and some wretchedly poor, should be taken up. Perhaps hospital abuse is not altogether the fault of the abusers, for when we see one institution competing against others in almost every large town in the country, each striving to show the largest number of patients, it is no wonder that the undeserving are as ready as those more properly speaking the fit recipients of charity, to take all they can get for nothing. It is, therefore, quite time that steps should be taken to lessen this fraud on medical charities and on the medical profession. We learn from the report that "with a view to minimise the tendency to resort to the institution on the part of persons who formerly did not do so, arrangements have been made for visiting the homes of persons living in Manchester and Salford, and inquiring into their means, with a view to eliminating those who ought not to be using the hospital." Note how delicately the point is put. The hospital is also going to charge cost price for cod-liver-oil emulsion to those who can afford to pay, but not to those who are too poor to do so. The medical report testifies to a record year's work both at the hospital and dispensary. The financial condition is anxious.

The Rigorous Temperatures of Factories.

A case of some interest and importance was heard at the Rochdale borough police court on March 24th. On Jan. 27th and 28th three waste manufacturers were summoned for "failing to take adequate measures for maintaining a reasonable temperature" in particular workrooms. Mr. Verney, factory inspector, visited the factories worked by the three defendants and found the temperature 36°, 33°, and 28½° F. There were no artificial means of heating which some firms had. The operatives at this kind of work were said to be poor and unorganised and so could not insist on better conditions. Dr. T. M. Legge of the Home Office said that the operatives ought not to be asked to work in a lower temperature than 50°. The solicitors for the three firms said it was unreasonable that artificial heat should be required, that it would be a great expense, in one case about £300, that the material would be more inflammable, and therefore more dangerous. The general plea was that no complaints were made, and that the insurance companies debarred them from using artificial heat. If there is so much danger of fire it is possibly from the great amount of dust in the air of the rooms, and this of itself is, perhaps, as bad for the health and comfort of the workpeople as the cold. One witness, when asked if he thought 36° a reasonable temperature, said, "Yes, I think they can work easily enough in that;" but to the question, "Would you like to work at that temperature?" he replied, "No, I should not," which may well be believed. The chairman said that the bench considered the temperature too low, but as these were the first cases heard in the district the small fine of 2*s.* 6*d.* and costs was inflicted in each case. Perhaps by next winter things may be better.

April 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The New Dykebar Asylum.

THE county of Renfrew's new asylum at Dykebar is now approaching completion, and it is expected that in a week or so part of it will be ready for the reception of pauper patients. Hitherto county patients have been boarded out at other asylums, but, the requisite accommodation at these latter places failing, the Renfrew district lunacy board were ultimately forced to provide accommodation for themselves. A purchase was made of the Dykebar estate, comprising 540 acres, situated between Paisley and Barrhead, and a suitable portion marked off for the erection of asylum buildings. The result has been the erection of one of the most complete and up-to-date establishments of its kind in the country. There are altogether ten main blocks of buildings, the chief being the central or administrative block with its two hospital wings. The most striking feature of the new asylum is that it is erected on the villa system, there being altogether four large villas, which allows of patients being segregated according to the different kinds of cases. The only other asylums in Scotland worked on this principle are Kingseat Asylum, Aberdeen, and Bangour Village Asylum, Edinburgh. The main buildings, all of red sandstone, are: administrative block of two storeys and attics, with one storey hospital wings on each side (42 beds in each wing); reception block (16 beds); laundry villa, two storeys and attics (50 beds); and three well-appointed large villas, two storeys and attics each (42 beds in each). The kitchen and laundry adjoin the administrative block and to the rear are the workshops. The accommodation will be for about 300 patients. The heating apparatus is on the Reck system and the total cost of the building is estimated at about £100,000.

Glasgow Hospital Sunday Fund.

The annual report of the Hospital Sunday Fund for 1908 has just been issued. The total income from church collections amounted to £4980, showing a decrease of £47 on the previous year. The sum set aside for the infirmaries was £4750, and this was distributed in proportion to the number of fully occupied beds in each infirmary. According to this plan the allocation was as follows: Royal Infirmary (591·3 beds), £2036; Western Infirmary (541·94 beds), £1867; and Victoria Infirmary (246 beds), £847. After meeting the working expenses this leaves a balance of £6 to carry forward to next year.

Opposition to the Acquisition of the Sidlaw Sanatorium by the Town Council of Dundee.

The acquisition of the Sidlaw Sanatorium by the town council of Dundee was opposed at a meeting of the executive committee of the Citizens Union held on March 26th. It was decided to ask the ward committees to convene meetings as urgently as possible and pass resolutions against the scheme on the ground of extravagance. It was also agreed to memorialise Lord Pentland, the Secretary for Scotland, and the Local Government Board asking that final approval should not be given to carrying through the agreement come to between the corporation and the sanatorium directors until the ratepayers of the city had had ample opportunity of considering the scheme in all its details. It is understood that the memorialists object to the mode of procedure followed by the town council and the directorate of the sanatorium in coming to an agreement, certain legal defects being alleged. The Dundee Landlords and Housefactors' Association is also opposed to the provisional order, on the ground that to change the incidence of taxation would be a breach of the agreement come to when the last provisional order was promoted, and under which it was arranged that there would be no alteration in this respect until 1914. A further meeting anent the matter was held at Auchterhouse on March 23rd. Complaint was made that Auchterhouse had in no way been consulted, as far as was known, while the matter concerned the village in several ways, drainage and water supply being mentioned. A letter was also read from Mr. D. Crichton, Dundee, who resided in Auchterhouse for several years, expressing indignation at the action of the Dundee town council in so hurriedly settling the matter, and saying that it was only possible to believe that the course was due to a desire to aid the directors to get rid of the institution under their care. Several disadvantages of the scheme were touched upon in the letter. After further discussion a resolution was submitted declaring that the scheme was a great menace to the interests and health of the district; calling upon the town council and the Airlie trustees to take measures for restricting as far as possible the number of consumptives to be treated, for confining them within the grounds of the sanatorium, for preventing the sewage of the institution from becoming in any way a nuisance or a danger to the health of the locality, and for insuring to the village a pure water-supply. The Airlie trustees were also to be asked to make no arrangements which would interfere with the present privileges of the inhabitants of Auchterhouse in regard to Auchterhouse Hill. This resolution was seconded and ordered to be communicated to the Dundee town council, county council, and the Airlie trustees.

April 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mortality in Irish Towns.

THE registration figures of last week show that the number of births (238) exceeded that of the deaths by 22. The mortality among the males, however, exceeded the male births by one, while 23 more females were born than the number of deaths of members of that sex. The deaths represented a rate of 27 per 1000. This figure was exceeded in Armagh and in Cork, in each of which cities it reached 27·5 per 1000, and in Kilkenny, where it attained the rather startling figure of 34·3. The deaths in Dublin included six from measles, four from influenza, two from whooping-cough, and one each from diphtheria, enteric fever, and enteritis. The deaths from tuberculous diseases fell from 46 in the previous week to 29, 22 of which were from decline. Of the deaths of children, 53 had occurred under four years of age, including 33 infants under one year and nine under one month. Among those of riper age 27 of the deaths were of persons over 60 years, 35 of persons aged 70, while there were six octogenarians, and one (a woman) who had passed 95. The deaths in Belfast numbered 198, which included five from whooping-cough, four from diarrhœal disease, and one from diphtheria. In Cork 40 deaths occurred, including two from enteric fever and one from whooping-cough. The rate exceeded 20 per 1000 in 12 of the 22 selected districts, and was below 10 in two only of these. The lowest was in Drogheda, the record there being 8·2.

Royal Victoria Hospital, Belfast.

At the annual meeting of the governors and supporters held on March 31st it was reported that 3336 new intern and 30,041 new extern cases were treated during 1908. The total income was £15,145 11*s.* 10*d.*, while the expenditure was £15,867 17*s.* 1*d.* It was mentioned that the Royal Victoria Hospital came out 48·48 per cent. cheaper than the average cost per bed in 12 principal hospitals in London, while compared with the average of 19 provincial Scottish and English hospitals it was 17·47 cheaper. In the Royal Victoria Hospital the cost per bed was £51, so that subscribers can see there is every effort at practising economy in the working of the hospital.

Health of Belfast.

At the usual monthly meeting of the corporation of Belfast on April 1st it was reported that between Feb. 14th and March 20th the death-rate was 20·3, that from zymotic disease 0·6, while from chest ailments it was 8·2 per 1000. There is a marked reduction in all notifiable infectious diseases, especially in typhoid fever. Compared with the same period of 1908 the death-rate is lower.

April 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Syphilis by Tartar Emetic.

AT a meeting of the Hospitals Medical Society held on March 19th M. Queyrat and M. Demanche communicated a paper, in which they said that, following up the ideas of those who had treated sleeping sickness and various forms of spirillosis with tartar emetic, they had been trying to see if this drug had any action in syphilis. The method of administration was by intravenous injection of a 1 in 1000 solution made isotonic by the addition of 7·50 grammes per 1000 of sodium chloride. The solution was injected very slowly by means of a bulb pipette, which had been sterilised in an autoclave, and an indiarubber bulb. Thanks to these precautions the two observers were enabled to give a daily dose for 11 or 12 days of from 0·10 to 0·12 of a gramme of tartar emetic without producing any inconvenient symptoms. In the first patient, who, besides having a marked secondary rash, was suffering from commencing pulmonary tuberculosis, the treatment had to be interrupted on account of its aggravating the pulmonary symptoms. In the second patient, suffering from both macular and papular syphilides, the papules rapidly disappeared, giving place to pigmented patches. In a third patient, who was covered with syphilitic psoriasis, the psoriatic patches became transformed into large pigmented plaques. Some days after the cessation of the antimony treatment the patient was attacked by acute meningitis. Lumbar puncture showed abundant leucocytosis with polynucleosis. A course of mercury rapidly cleared up the meningitis, thereby confirming its syphilitic nature. Finally, the two observers say that the treatment by tartar emetic is, as a rule, well borne by syphilitics, that it greatly improves certain cutaneous manifestations of the disease, but that it apparently has no specific action on the progress of the disease nor any influence in retarding the appearance of complications.

The Abuse of Disinfection in Paris.

At the same meeting of the Hospitals Medical Society M. Comby raised a protest against the compulsory notification of measles and the resulting disinfection. Measles, he said, although an infectious disease, is the very last which calls for disinfection. Even though it is contagious before the rash appears, the infection lasts but a short time, and the organism cannot exist outside the body and therefore does not live in furniture, flooring, or walls. Disinfection is therefore useless. Grancher had succeeded in preventing the Academy of Medicine from including measles among the diseases to which compulsory notification should apply, but in 1903 the Academy had gone back on this decision. M. Lemoine, professor at Val de Grâce, was not only convinced of the uselessness of disinfection of dwellings in measles, but he had great doubts as to its utility in other infectious disorders. M. Courmont, the chief of the disinfection office in the department of the Rhone, said that measles should be eliminated from the list for disinfection. In Paris disinfection as carried out by the municipality had not fulfilled expectation. M. Comby concluded by saying that the Academy should revoke its decision of 1903 by taking measles out of the list of diseases for compulsory disinfection.

Sterilisation of the Skin with Tincture of Iodine.

At a meeting of the Surgical Society held on March 24th M. Walther reminded his audience of his method of sterilising the skin by means of tincture of iodine. In every case in which he had employed this method—they were mostly laparotomies—he had obtained excellent results, with primary union of the skin. He concluded his paper by giving an account of the experiments which he had made, and of the bacteriological and histological results at which he had arrived.

Cerebro-spinal Meningitis.

Last week I informed your readers that Dr. Netter had pointed out to the Academy of Medicine that Paris was threatened with an epidemic of cerebro-spinal meningitis. At a recent meeting of the Hygienic Committee Dr. Thoinot reported that since Jan. 1st there have been 51 cases in the department of the Seine. Dr. Thoinot, however, does not consider that there is a real epidemic, for the cases were widely scattered. The police authorities are taking all precautions, and the director of the Assistance Publique has issued orders that all adult cases of the disease are to be taken to the Claude Bernard Hospital and those of children to the Trousseau. The best remedy appears to be the serum introduced by Wassermann of Berlin, which, thanks to the exertions of M. Roux, has been made use of in France. Numerous recoveries have occurred under its use.

The Venoms of the Salamander and the Viper.

Madame Phisalix appears to have just made a curious discovery. She has been studying the relations which exist between the venom of the salamander and that of snakes, and on March 27th M. E. Périer gave an account of her researches before the Academy of Sciences. The venom of the salamander is a convulsant, that of the vipers, on the contrary, is a narcotic (*stupéfiante*). Madame Phisalix inoculated an animal with a dose of both poisons and to her surprise the animal remained unharmed. Salamander venom therefore, according to these researches, neutralises viper venom. The salamander, too, is immune to viper poison.

The New Morgue.

The Prefect of the Seine, after consultation with the Ministers of Justice and of Public Instruction, has just appointed a commission to draw up a complete scheme for the reorganisation of the Morgue. The commission consists of 25 members, among whom are Professor Landouzy, Dean of the Faculty of Medicine; M. Le Chatellin, Professor at the Faculty of Sciences; and M. Thoinot, medical inspector of the Morgue.

Nebulised Fluids in the Lungs.

At a meeting of the Academy of Medicine held on March 22nd M. Gauthier read for M. Cany a note on the Penetration of Nebulised Fluids into the Lungs, recording experiments which seem to show that substances in the form of spray do penetrate into the recesses of the lungs.

April 5th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The International Ophthalmological Congress.

NOWHERE are congresses, scientific and professional, domestic and international, more frequently held or more numerously attended than in Italy, where they seem to assume the place of "post-graduate courses," which, in a sense, they may be said to have anticipated. They supply, indeed, the information and the discussion which in other European countries are conveyed in medical journals—a form of professional literature in which Italy is as yet comparatively poor. Naples is to-day the seat of one of the most important and attractive of these—the Congresso Internazionale Oftalmologico, the eleventh of the series—which under the honorary presidency of the Senator Giovanni Paladino, professor of physiology and rector of the University, met this forenoon to the number of 550 in which the leading ophthalmological schools of nearly all nations were worthily represented. Addressing an audience reinforced from all the faculties of the Neapolitan seat of learning and including many of the most distinguished citizens, Professor Paladino announced a message from the King, embodying His Majesty's best wishes for the success of the "nobile riunione," followed by a congratulatory letter from the Minister of Public Instruction. From this Professor Paladino launched into a review of the progress of ophthalmological study and practice in Italy, more particularly as illustrated in Naples, beginning with Giambattista della Porta, who, after having invented the *camera oscura*, recognised (he said) "in the *globo oculare* a special *camera oscura*, thus opening up a sure pathway to the minuter study and knowledge of the physiological mechanism of vision." Having given a cordial welcome to the *congressisti* present he then declared the Congress opened in the name of the King. Next to speak was the venerable Senator Tommaso Senise, professor of pathology, who welcomed the *congressisti* on the part of the Neapolitan Medical School and expressed the hope that their presence would stimulate the *genius loci* to continuing, if not improving upon, the past achievements of Naples in ophthalmology, achievements giving honour to the names of Castorano, Del Monte, and De Vincentis. After a few cordial words from the representative of the Neapolitan municipality, Dr. de Lapersonne, professor of ophthalmic medicine in the University of Paris, spoke in the name of the foreign delegates, dwelling felicitously on the *fratellanza* of science, particularly of medicine, and evoking rounds of applause by his eulogy of the manifold attractions of Naples and of the *antiqua mater*, Italy. Finally, Dr. Angelo Angelucci, who holds the chair of ophthalmology in the Neapolitan School, rose as "working president" of the Congress to wind up the proceedings, and after a touching reference to the Siculo-Calabrian cataclysm and to the magnificent demonstration of sympathy and practical relief it had evoked from the outlying world, he concluded by auguring well for the department of medicine which the Congress represented, a Congress exceeding in numbers and in point of *personnel* not falling below the most brilliant of its predecessors. In the afternoon the special business of the day began, among the monographs presented being two of exceptional interest by Dr. Umberto Bruni of Naples, the first on "Una Speciale Cura del Trachoma" and the second on "La Correzione dello Strabismo senza Operazione."

The International Congress on Injuries to Working-men.

This Congress, the second of a series which met for the first time at Liége, will be held in Rome, under the patronage of the Italian Government, from May 23rd to 27th next. It will have two honorary presidents, Dr. Guido Baccelli, Member of Parliament and director of the Roman medical clinique, and Professor Francesco Durante, Senator of the Kingdom and head of the surgical clinique in the same seat of learning. The honorary vice-presidents are also men of light and leading, while the "acting president" will be Professor Salvatore Ottolenghi, director of the Institute of Legal Medicine in Rome. A strong executive committee in which the schools of all the divisions of the Italian kingdom, mainland and insular, Northern, Central, and Southern, are represented, has been organised to cöoperate with the two other committees, domestic and foreign, charged with the carrying out of an exceptionally interesting and comprehensive agenda paper. Those of the English-speaking world who desire to intervene at the Congress are requested to apply by letter, inclosing a postal order for 20 francs, to Professor Attilio Ascarelli, treasurer to the Congress, at 38, Via Borgognona, Rome.

The Health of the Pope.

His Holiness, I am happy to announce, is now well enough to take outdoor exercise, in spite of the weather, which continues variable, not to say inclement. On the morning of April 1st, for the first time after several months, he was able to enjoy an outing in the gardens of the Vatican. Leaving his apartments at 10.30 he crossed the Museo del Lapidario and reaching the Cortile della Pigna he walked about for half an hour. Then he entered his carriage and made a round of the beautiful demesne on which the belated spring has not yet set its mark, thereafter returning to his apartments a little before noon, not too tired to receive in private audience Cardinal Gotti and the Bishop of Macerata.

The Maladies of Prehistoric Man.

There never was a time, according to Celsus in his admirable introduction to the "De Medicina," when the healing art was not in request, and another great light of Roman literature, the poet of the "De Rerum Natura," has imagined for us the lesions of primitive man in his conflicts with wild beasts. It is, indeed, such injuries that must have first exercised the resources of medicine and made surgery the elder sister of the art—the younger being that which dealt with internal or "constitutional" disease. Of this latter, as met with in prehistoric man, the Subalpine School has recently been taking cognisance as a branch of those researches which have lately been prosecuted in Sicily and in Cyprus by the distinguished physiologist Professor Angelo Mosso. Paul Broca had already shown that tuberculosis must have been of primeval occurrence, judging from the ankylosis found in the knee-joint consequent on a so-called "white tumour," while signs of advanced caries due to a similar cause he also recognised in the lower limb. Le Baron discovered and described a jaw-bone bearing lesions consequent on cancer; but it is arthritis in every form, central and collateral, that has been most often and most clearly diagnosed. [illegible] primitive indeed but real, for the neolithic patient?" Such is the question answered in the affirmative by one of Mosso's disciples. True, the intervention of clinical surgery, as we understand it, was possible only in far more recent times. An arrow-head, for example, imbedded in a bone was not extracted, but the so-called "cure" took the form of rest and restorative nourishment for the sufferer. "White tumours" (tuberculous in origin) were allowed to cure themselves by ankylosis (as Broca pointed out)—ankylosis resulting in rigidity of the joint and limb, only obtainable by the repose and the nutriment aforesaid. Whether or not other special cures were in practice cannot be made out with certainty, though it is significant that many of the severely wounded must have survived their lesions and that a high percentage of fractures must have been conducted to complete reparation. Skeletons, moreover, are in evidence with the traces of chronic surgical maladies, maladies of long duration, which testify to the patients having been under some system of cure, protected in the struggle with the ailment or even artificially sustained during its progress. Man, even in his primeval stage, must have had some other resources to fall back upon than the *vis medicatrix naturæ*, resources the character and enumeration of which are in course of investigation by that school from which Mosso has already taught us to expect good results, embodied in the "Atti" of the local Academy of Medicine.

Messina Rediviva.

The Senator Francesco Durante, the veteran head of Roman surgery, theoretical and clinical, has just been entertained at a banquet by his colleagues, including Dr. Guido Baccelli, professor of clinical medicine, the Senator Dr. Stanislas Cannizzaro, who holds the chair of chemistry in the same school, and many other friends and sympathisers, prominent among whom were the representative of the Knights of Malta and the distinguished jurist Signor Manfredi, President of the Upper Chamber. The spokesman of the occasion was Dr. Giuseppe Sergi, professor of anthropology, who in the name of the teaching staff of the Roman school, the students past and present, and the Sicilian compatriots of the guest of the evening, gave an eloquent appreciation of the many boons conferred on science, on professional practice, and on civic life by Francesco Durante. The toast having been enthusiastically honoured the Senator Durante replied. He had all his life, he said, been devoted to the welfare and the interests of his fellow man, primarily in the alleviation of physical suffering, and it was in keeping with his past career that he should henceforth dedicate the years that might still be in store for him to the resuscitation and prosperity of his beloved Messina, so recently visited by so terrible a calamity. Dwelling with power and pathos on the theme, he invited the company to join him in drinking to "Messina Rediviva," whose regeneration, moral no less than economic, was a task of the immediate present and would be (he doubted not) a triumph of the near future.

April 2nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Disinfection in Vienna after Infectious Diseases.

LAST year new regulations were laid down by the health committee as regards the disinfection of household furniture and rooms in which an infectious patient had been treated, and Dr. Böhm, in a paper read before this committee, reported on the working of the new rules. All disinfections are, as a rule, carried out by order of the local magistrate and are therefore free to the public, but in special cases, when disinfection is required by a private party, a small charge is made. As regards the system in use, the disinfection of inhabited places is effected by means of a formaldehyde atmosphere, produced mostly by vaporisation or sometimes by a spray apparatus. The other usual methods are too dear, except in paid cases, and are used only in rooms where special precautions are necessary to prevent an outbreak of fire. The other chemical used is oxycyanide of mercury. Its disinfecting power (1/10—5/10 per cent. solutions are sufficient) is powerful enough to make its employment cheap; at the same time a very great advantage is found in its absolute lack of any odour, and the material (including metal) to be disinfected is not affected. The disinfecting staff receive a 5 per cent. solution and have only to weaken the liquid as required. The public, however, is not allowed to handle the substance because of its poisonous characters. Hitherto, no bad effects from this method have been noticed and the health of the men engaged in the work has not suffered. Portable personal belongings are disinfected by means of steam in special apparatus, of which there are at present six very large plants available in Vienna, all working with high-pressure steam. Special precautions are taken to prevent any possibility of the disinfecting staff themselves carrying diseases into other places. Personal cleanliness, special clothing, and baths after work are required of them. The amount of work done during the time the new rules have been in force is not small. From the end of May until the end of December, 1908, 11,649 rooms in lodgings were disinfected, and 79,387 articles belonging to 9170 persons were treated by steam with perfectly satisfactory results.

Prohibition of the Use of Yellow Phosphorus for Matches.

The Government has laid before the House of Parliament a Bill dealing with the prevention of the use of yellow phosphorus in the manufacture of matches. Austria and Japan are the only two important match-producing countries who have not signed the Convention of Bern regulating this branch of industry, and severe recriminations were directed against the Ministry of Commerce by the Labour party for this alleged neglect of the interests of the workers. A few days ago the long-expected Bill was brought in. In this the Government proposes to refuse permission for any new match factory to use the yellow or white phosphorus, and to stop the use of this material in the existing factories after July 1st, 1912. The investigations of the committee for the study of phosphorus necrosis[1] showed the deleterious effect of this manufacture upon the health of those engaged in it, in spite of very stringent precautions against poisoning. The memorandum drawn up by this committee, and presented by the Vienna Gesellschaft der Aerzte (Medical Society) to the Government, has had a very marked effect upon the decision of the latter; the Bill will be carried with a great majority.

Regulations for the Sale of Caustic Potash.

The Vienna Gesellschaft der Aerzte is also to be thanked for another important reform taken up by a specially appointed committee to prevent the frequent accidents which occur from drinking caustic potash by mistake. The investigations of the body appointed for this purpose have resulted in the adoption of a uniform strength of the solution (1·25 per cent.) as the standard solution for trade; this can be sold free from restrictions. Any stronger solution necessitates the vendor adopting certain precautions, transgression of which will make him liable to punishment. The liquid must not be sold to children under 16 years. It must be kept and sold in bottles having a different appearance from the bottles used generally for beverages. The contents of the vessel must be stated clearly on a prominent label, as well as the percentage of the liquid. The use of the potash in household work should be discouraged, according to the suggestions of the committee, by adding to it an unpleasant-smelling substance, which would also prevent people from drinking it. By order of the Ministry of the Interior the above-mentioned regulations have already been put in force. The importance of the action thus suggested by the medical corporation may be judged by a few figures. Within the last five years not less than 370 cases of injuries by swallowing caustic potash have been treated in Vienna hospitals alone. It is true, there were many cases of attempted suicide amongst them, and these persons would have selected some other means of self-destruction if they had no access to this liquid, but there were still quite sufficient persons who inadvertently partook of the poison to make precautions as to sale necessary. It be added that in the cases of poisoning, although immediate effects were not always fatal, the results often been fatal indirectly, by subsequent inanition, d œsophageal injury.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Pellagra in the United States.

A RECENT report of the Public Health and Marine Ho Service of the United States Treasury Department anno that a disease having the characteristics of the pella Southern Europe has appeared in the southern states a spreading rapidly. Under the auspices of the State Bo Health of South Carolina a conference was recently h which this new disease was discussed in all of its aspec every effort was made to dispel the mystery surroundi origin. It was estimated that there were at least 500 c the State of South Carolina. The theory was advance the disease is due to the use of damaged corn (maize food. The corn is rendered unfit for food by the m intensive methods of farming by which the c harvested while the grain is unripe and putrefaction as a result. This theory prevails in the Lombard Piedmont districts of Italy, the hotbed of pellagra the Italian Government has issued instructions to p this defect in the harvesting of corn. This theo denied by some members of the conference in Carolina, who asserted that from their own observation are extensive regions to-day where pellagra is rampa where corn is neither grown nor used as a food, while, other hand, there are large areas where this cereal principal article of diet, with all of its fungi and ba but pellagra is unknown. The conclusions of the con were directed towards an immediate and widespread s the disease.

Increase of Cancer in New York.

Dr. Harvey R. Gaylord, Director of the New York Cancer Laboratory at Buffalo, reports to the State ment of Health that the increase of cancer in th of New York is little short of appalling. The a death-rate per 100,000 population for 1906, 1907 1908, taken collectively, is 76, showing an increase years—from 1896 to 1909—of 28·8 per cent. Durin same period the death-rate from tuberculosis has dimi 9·1 per cent. The Director attributes the difference death-rate of these diseases to our knowledge of the tious character of tuberculosis and the well organised w which is being opposed compared with our knowle cancer. There are but three institutions in this c devoted to the study of cancer exclusively besides th York Laboratory, and the total expenditure in research by these four institutions is less than $ annually.

The Centenary of the Birth of Dr. Oliver Wendell Hol

The centenary of the birth of Dr. Wendell Holmes fa August 29th, but circumstances have induced the Cam Historical Society to select April 27th as the day of brating the occasion. One of the interesting features w the attendance of the students of the medical depar during the period that Dr. Wendell Holmes filled th fessorship of anatomy, 1841–1882. President Eliot of H University will preside, and Dr. Edward Waldo Em son of Ralph Waldo Emerson, will give the principal ad

The Prevention of Ophthalmia Neonatorum.

Ophthalmia neonatorum as a cause of blindnes attracted wide attention in this country and as a preventive measures are being advocated in many o States The most recent expression on the subject is t American Public Health Association in an elaborate r From this report it appears that about 28·69 per cent. new admissions to ten schools in eight States and Province of Ontario, Canada, in 1907, were needlessly In the Pennsylvania School for the Blind the averag centage of eight years' admissions was 33·36 of ophth neonatorum. The conclusion of the committee is tha

---

[1] Vide the Vienna letter in THE LANCET, May 30th, 1903, p 1591.

Responsibility for the control of this infective disease rests with the health authorities throughout the country, and it approves of the recommendations of the American Medical Association, which are briefly: (1) the enactment of laws in each State and federal territory requiring the registration of births and placing the supervisory control and licensing of midwives in the boards of health; (2) the distribution by health boards of circulars of advice to midwives and mothers, giving instructions as to the dangers, methods of infection, and prophylaxis of ophthalmia neonatorum; (3) the preparation of receptacles containing the chosen prophylactic with specific directions for its use; (4) the maintenance of proper records in all maternity institutions and other hospitals in which children are born, of the number of cases of ophthalmia neonatorum, with the method of treatment, and the results; and (5) periodic reports to boards of health by all physicians engaged in obstetrics of the number of cases of ophthalmia neonatorum that have occurred in their practice within a specified time, what prophylatic measures were employed, and with what results.

The Administration of the Pure Food Law.

The Pure Food Law is giving rise to interesting decisions of the courts, relative to the duties of boards of health and health officers. In a suit to enjoin the city of Chicago and its officials from summarily seizing and destroying food in cold storage as unfit for human consumption, the court held that provision for a hearing before seizure and condemnation and destruction of food which is unwholesome and unfit for use is not necessary; that the [illegible] is unfit for human consumption should be summarily seized and destroyed to prevent the danger which would arise from eating it. It was contended that there was no emergency in this case requiring speedy action for the destruction of the poultry, as the food was in cold storage and would continue in the same condition for three months, and therefore the defendants had ample time to give notice to the owner and have a hearing as to the condition of the food. But the court held that if a hearing is to be always necessary the question arises as to what is to be done with the food in the meantime. Is it to remain with the cold storage company, and, if so, under what *security that it will not be removed?* As the legislature made no provision for a hearing, and as [illegible] ply protected against the party [illegible] ent action, the court sustained summary proceedings.

What is an Accident?

A physician of New York has made a claim for insurance money on the basis of an attack of appendicitis caused by [illegible] of solder. The patient, [illegible] mouth while eating his [illegible] with his teeth swallowed [illegible] cute appendicitis and at the operation the appen[illegible] a mass of solder, which lay in t[illegible] portion protruding through the [illegible] vidences that there had been any previous disease of the organ. On recovery the physician made a claim against the insurance company for an accident. Commenting on the case the surgeon, Dr. Robert T. Morris, states that in this case we have a question bearing on the matter of accident insurance which may call for a new adjudication of the word "accident," and he contends that perforation of the appendix by the lump of solder accidentally swallowed was not materially different from a perforation that might have occurred from the accidental discharge of a pistol carrying the solder as a missile.

March 26th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Friendly Societies and the Medical Profession.

REPRESENTATIVES of the medical profession and the [illegible] Wellington recently to try [illegible] as to fees and con[illegible] l for from the meeting, but unfortunately the hope was not fulfilled. The main point—namely, that an arbitration court might be set up which would deal with all disputes between the profession and the societies—was not finally settled. If some general agreement could have been come to regarding this it would have been an excellent thing, because the spectacle of medical men fighting unions in the lay press is never edifying. Something, however, has been accomplished in the direction of a common understanding, and perhaps another meeting will see this most desirable arrangement made secure.

The Registration of Births and Deaths.

A Committee of the Upper House, presided over by the Honourable Dr. Collins, sat and inquired into the question of whether some alteration should not be made in the matter of the registration of births and deaths. By an Act of last year it was provided that:—

> 1. It shall be the duty of the occupier of any house in which a child is born alive to give notice of the fact of the birth, the date on which it [illegible] and the name of the mother or father of the child, to the [illegible] registered [illegible] a city or [illegible] is section

Evidence was given by the Registrar-General generally against any alteration. As the law now stands registration of a death need not be made before 31 days have elapsed. One consequence of this is that a person may have been buried some weeks before he is officially dead. The scattered nature of the population was urged as a reason why it was not feasible to lessen the time; but it was pointed out that the conditions which obtained when the present law was passed did not now exist, and that there is no reason why notification of the birth or death should not be made within three days by registered post. All the medical witnesses insisted upon the necessity for an alteration in the law. The Chief Health Officer pointed out the difficulties which existed in the checking of infectious disease through the long delay. Some interesting evidence was given by a local undertaker, who assured the Committee that he always made certain that his subject was "completely dead" before he placed him in his coffin. The setting up of the Committee was occasioned by the suggestion that sometimes live persons had been interred. It would seem from the evidence given that this danger was small except in the case of so-called stillborn children. It is to be hoped that some alteration in the law may result. Several witnesses insisted that the medical man should see the dead body before he gives his certificate. This undoubtedly could easily be done in the larger centres in deference to the general feeling that the practice of giving a certificate of death on the statement of a friend or relative of the deceased is entirely wrong.

The Dentists' Association.

The annual meeting of the Dentists' Association was held in Wellington on Jan. 4th. The question of the medical inspection of school children was much in evidence and some very important data were submitted with reference to the condition of the teeth of the children attending the State schools. The President, Mr. A. Hoby, dealt very exhaustively with this matter in his presidential address. The Chief Health Officer, Dr. J. M. Mason, who presided at the opening, in the course of his speech dwelt upon the rightness of the rule which prevents members of the profession from advertising. The meeting was followed by a dinner at which several Ministers of the Crown were present.

Obituary.

By the death of Dr. R. H. Bakewell of Auckland the profession in New Zealand has lost one of its oldest members. For some time past he had been unable to do much in the way of general practice, but he always wielded a ready and sometimes sarcastic pen. Dr. Bakewell had a very varied experience. Serving as surgeon in the Crimean war he was court-martialled for writing letters to the newspapers. He then became a general practitioner in England and subsequently was appointed health officer at Trinidad. Finally he settled in New Zealand, where he practised for many years. He volunteered for service when the Boer war broke out, but whatever he was he was always a voluminous contributor to

THE Bath board of guardians has granted *superannuation allowance to Mr. J. Davies, M.R.C.S. Eng* L.S.A., who for the past 36 years has been medical offic for the No. 1 district.

THE Paris Academy of Medicine has electe Dr. Courmont of Lyons and Dr. Oddo of Marseilles as corr sponding members. The candidate who obtained the ne highest number of votes was Dr. Collignon of Cherbourg.

MEDICAL MAGISTRATE.—The Lord Chancell has placed the name of Mr. John M. Cuthbertson, L.R.C Edin., F.F.P.S. Glasg., of Droitwich, on the commission the peace for Worcestershire.

DONATIONS AND BEQUESTS.—The Rev. Howse has by will bequeathed about £25,000 to Guy's H pital.—The late Mr. G. Smith, M.R.C.S. Eng., L.D.S., has by will, subject to a number of bequests, the residue of estate (£11,699), to be equally divided between the Ro Infirmary, Manchester, and University College Hospit London. The money is to be used for the benefit of one more of the surgical or dental staff of the institutions me tioned who may be incapacitated from their work by havi become infected by any puncture or contracted blo poisoning whilst examining or operating on patien or after conducting post-mortem examinations.—By t will of Miss Frances Margaret More £1000 are left the Royal National Hospital for Consumption and Diseas of the Chest, Ventnor, Isle of Wight, and like sums to t Adelaide Hospital, Dublin, and the Royal Isle of Wig Infirmary, Ryde. The St. Patrick's Home for Nurse Dublin, receives £500.—Mrs. Annie Tomlinson, of We Hampstead, has bequeathed £1000 to the Cardiff Infirmary.—Under the will of the late Mr. John Kershaw, F.R.C.S. Edin. a sum of about £50,000 has been left for the purpose establishing a hospital at Royton, Lancashire. The testat desires that "any such hospital and infirmary may as fa as practicable be free and open to all applicants, and tha no inquiry be made in any case as to the religious belief o applicants or whether they attend the services of any churc or chapel, also that no clergyman or minister of religion o any Socialist or person known to hold or profess Socialis opinions be at any time a trustee, director, or manager o the said hospital and infirmary."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Acts Amendment Bill.

THE text of the Medical Acts Amendment Bill, which was recently introduced in the House of Commons by Mr. COOPER, has now been issued. As was explained in THE LANCET of last week the object of this Bill is (1) to require a medical practitioner applying for registration on or after J
1911, to submit evidence of having received
practical instr
administration of anæsthetics; (2) to pro-
hibit any pe
medical practitioner administering an
anæsthetic
conditions; (3) to safeguard the rights

of all persons registered as dentists before the commencement of the Act; and (4) to prohibit any certificate of death being given in the case of any person dying under an anæsthetic.

The principal clauses of the Bill refer so directly to a subject which has engaged the close attention of the medical profession recently that they may be quoted *in extenso.* They are as follows.—

"Clause 1. On and after the *first day of January, one thousand nine hundred and eleven*, no person shall be registered under the Medical Acts in respect of any qualification referred to in any of those Acts unless he shall have produced evidence that he has received theoretical and practical instruction in the administration of anæsthetics.

Clause 2. Any person not a registered medical practitioner who shall
her person, by inhala
ixture of drugs, solid
sciousness during any
procedure, or during
childbirth, shall be liable on conviction before a court of summary jurisdiction for such offence, to a penalty not exceeding *ten pounds*, and, in the case of any subsequent conviction, to a penalty not exceeding *twenty pounds:* Provided that a person shall not be liable to a penalty under this section if in conducting such administration he was acting under the immediate direction and supervision of a registered medical practitioner, or if the circumstances attending the administration were such that he had reasonable grounds for believing and did believe that the delay which would have arisen in obtaining the services of a registered medical practitioner would have endangered life.

Clause 3 Power is hereby given to the General Council to make any regulation or order to carry out the requirements of this Act.

Clause 4 Any registered medical practitioner who gives a certificate of death in the case of any person dying while under the influence of an anæsthetic shall be liable, on summary conviction, to a penalty not exceeding *five pounds*.

Clause 5. Nothing in this Act shall prohibit a person registered under the Dentists Act, 1878, *before the commencement of this Act*, administering an anæsthetic during a dental operation or procedure"

Clause 6 provides that offences under the Bill may be prosecuted in the manner provided by the Summary Jurisdiction Acts, and lays down a corresponding procedure for Scotland and Ireland. Clause 7 defines the expressions "Medical Acts," "General Council," and "registered medical practitioner." The expression "General Council" means the General Council of Medical Education and Registration in the United Kingdom Although the Bill is called "the Medical Acts Amendment Bill" Clause 8 lays down that when passed it may be cited as "the Anæsthetics Act, 1909

Necessitous Mothers (Assistance) Bill

Mr. ROBERT HARCOURT has introduced into the House of Commons a Bill "to empower local authorities to make provision for the assistance of necessitous women in contemplation of, and after, childbirth" The Bill, which was read a first time, gives local authorities power to levy a rate not exceeding 1*d.* in the £ to assist necessitous women during pregnancy and childbirth and *for a short time afterwards with food*, medical help, and nursing, the women agreeing to comply with regulations as to ceasing work for wages and to obey the orders of the nurse or medical man appointed by the authorities.

The Medical Treatment of Elementary School Children.

The Local Education Authorities (Medical Treatment) Bill, which has been introduced into the House of Commons by Mr. WALTER GUINNESS, has the support of a large number of Members on both sides. Its object is "to provide for the recovery by local education authorities of costs for medical treatment of children attending public elementary schools in England and Wales." It has been read a first time. The Members "backing" the Bill are Mr. ADKINS, Mr. BRIDGEMAN, Lord ROBERT CECIL, Mr. FELL, Mr. HENRY GOOCH, Mr LEIF JONES Mr RAMSAY MACDONALD, Mr. MADDISON, Mr. PEEL, Mr. VIVIAN, and Mr. WHITWELL WILSON

Infant Life Protection Bill

Lord ROBERT CECIL has presented in the House of Commons a Bill "to prevent the destruction of children during birth" The measure, which has been read a first time, is backed by Mr. SHACKLETON, Mr. CHIOZZA MONEY, and Mr. SIMON.

The Superannuation of Asylum Officers in Scotland.

Sir JOHN JARDINE'S Bill to provide for the grant of superannuation allowances to officers and servants of public and district asylums in Scotland has received the support of a large number of Members sitting for Scottish constituencies It was presented and read a first time in the House of Commons on Thursday, April 1st.

HOUSE OF COMMONS.

THURSDAY, APRIL 1ST.

Deaths from Uncertified Causes in the Highlands.

Mr WEIR asked the Lord Advocate to state the number of deaths from uncertified causes in each of the Highland crofting counties during each of the last five years.—Mr. URE replied (by written answer): The information desired by my honourable friend is as follows —

Deaths from Uncertified Causes in each of the Highland Crofting Counties during each of the five years 1903-07.

County	1903	1904.	1905.	1906.	1907.
Shetland	156	126	123	86	100
Orkney	52	65	39	49	46
Caithness	45	41	41	34	44
Sutherland	92	72	90	81	98
Ross and Cromarty	327	293	304	293	307
Inverness	337	279	258	251	261
Argyll	137	99	82	93	100

Escapes from Asylums

Mr. CHIOZZA MONEY asked the Secretary of State for the Home

whether they had yet presented a report on the subject—Mr.

The Consolidation of Public Health Law.

Mr. REES asked the President of the Local Government Board whether the Government proposed to consolidate the law regarding public health so as to bring together in one Act the different enactments relating to this subject—Mr. BURNS furnished the following answer I appreciate the advantage there would be in consolidating the Public Health Acts, though it would probably be found necessary in the first instance to amend them in some respects. I shall be glad to take steps in the direction indicated when opportunity offers, but I do not think it will be practicable to deal with the matter during the present session.

MONDAY, APRIL 5TH.

The Ambulance Service of the Metropolis.

In reply to Sir WILLIAM COLLINS, the Secretary of State for the Home Department stated that the valuable report presented by the committee on this subject had been received, but owing to the pressure of current work he could hold out little hope of dealing with the main recommendations, which involve legislation, in the present session.

Housing and Town Planning Bill.

Mr BURNS, in moving the second reading of the Housing and Town Planning Bill, said that it was a new departure in legislation and he regretted that it had been so long delayed The lack of some such measure 50 or 100 years ago affected the physique, the morals, the

recently one half of them had no medical officer The Bill laid down that every county council sho

erty which might be owned

his speech that one of the
t went—was that the Local
was to be a medical officer
of the best things that could
alth and he had contended
for it for some years The county councils would now have a special expert to guide them in regard to the very difficult and responsible duties which devolved upon them with regard to public health and housing. Medical officers of health

had been doing good work, many of them under difficulties and in face of the opposition of those who employed them. He was therefore glad that they were to have a security of tenure, that they were not to be dismissed except with the consent of the Local Government Board, and that they would be whole-time officers. However, these conditions were not to be given to the medical officers who had been appointed for the smaller local authorities—some of them at salaries of £20 or £30 a year. These men had had a hea [illegible] They were the weaker links in the chai [illegible] The county medical officers were the [illegible] the right honourable gentleman could [illegible] these weaker links in the chain. Howev [illegible] of tenure and the right of appeal to the Local Government Board in case of wrongful dismissal, he would be doing a great work. In some smaller rural and urban districts at the end of 12 months a medical officer was dropped because he [illegible] of interfering in the interests [illegible] members of the council who [illegible] gentleman knew that there were cases where medical officers were not reappointed by district councils because they were doing their best to bring about a better state of housing in the district. That was a scandal which ought to be removed, and could be removed by a stroke of the pen if the right honourable gentleman would consent to insert a provision in the Bill giving these medical officers the right to appeal in cases of dismissal. At the present time medical men had a kind of union by means of which they were trying to prevent members of their profession from taking up appointments from which others had been wrongfully dismissed. To give a right of appeal to these medical officers against wrongful dismissal would be a great step in advance, and would render them more independent and able to discharge their duties according to their conscience. He hoped that a number of amendments would be inserted in the Bill to give effect to the views which he had put forward on this subject.

Mr. Lane Fox moved a reasoned amendment to the motion for the second reading, declining to throw fresh charges on the local rates.

Mr. Hicks-Beach seconded.

Sir J. Dickson Poynder thought that the provision with regard to medical officers of health was one of the most important in the Bill. The Bill in its revised form established them on much more favourable terms than were originally proposed. The medical officer of health for the county had now under the Bill power to go all over the county area and inspect wherever he desired exactly on identical lines with the medical officers of health in the districts. This would give a great incentive to the exposure of bad sanitary conditions in country districts. As there was to be a Committee of Public Health and Housing attached to every county council there would be a regular established system supervising public health and housing in the counties, which was bound to improve the conditions.

After considerable discussion the amendment was defeated by 128 votes to 20, and the Bill was read a second time.

Appointments.

Succ[illegible]itutions, [illegible] mn, are [illegible] the Sub- [illegible] of each

Bateson, Henry, M.D., C.M. Edin, has been appointed Medical Officer for the Walkden and Worsley Districts by the Barton Board of Guardians.

Stiff, Harold, M.B. Cantab., has been appointed Surgeon to the West Suffolk Hospital, Bury St. Edmunds.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ashton-under-Lyne District Infirmary.—Junior House Surgeon. Salary at rate of £75 per annum, with board, residence, washing, &c.

Birkenhead Union Infirmary and Sanatorium.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

Birmingham General Dispensary.—Resident Surgeon, unmarried. Salary £170 per annum, with rooms, fire, lights, and attendance.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum.

Bristol General Hospital.—House Physician, Casualty House Surgeon, and Assistant House Physician for six months. Salary £60, with board, residence, &c.

Brixton Dispensary, Water-lane, S W.—Resident Medical Officer, unmarried. Salary £150 per annum, with apartments, attendance, &c.

Brown Animal Sanatory Institution.—Superintendent. Salary £300 per annum.

Burslem, Haywood Hospital.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and laundry.

Bury Infirmary.—Junior House Surgeon. Salary £80 per annum, with *board, residence, and attendance.*

Bury St. Edmunds, West Suffolk General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

[illegible] Salary at rate of [illegible]

[illegible] Hendon, N.W.—Salary £110 per [illegible]

Croydon General Hospital.—Honorary Medical Officer of the Ear, Nose, and Throat Department.

Dumfries and Galloway Royal Infirmary.—House Surgeon and Assistant House Surgeon. Salaries £80 and £40 per annum respectively, with board and washing.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £60 per annum, with board and washing.

Hampstead General Hospital.—Medical Officer in charge of the X Ray and Electrical Department. Salary 25 guineas per annum.

Hartlepools Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Hastings, St. Leonards and East Sussex Hospital.—Physician. Also Assistant Physician.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Salary £25.

Hospital for Sick Children, Great Ormond street, London, W.C.—House Surgeon; also Assistant Casualty Medical Officer; both unmarried, for six months. Salary in each case £30, with board and residence.

[illegible]

Lambeth, Parish of.—District Medical Officer. Salary £50 per annum, with fees.

Lanark Middle Ward Isolation Hospital, near Motherwell.—Physician Superintendent. Salary £200 per annum, with board, &c.

Lincoln Hospital for Mental Diseases.—Assistant Medical Officer. Salary £100 per annum.

London County Council Girls' Industrial School, 56, Brixton Hill, S W.—Medical Officer. Salary £45 per annum. Also Dentist. Salary £15 per annum.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £60 per annum, with board and residence.

Manchester, Chorlton-upon-Medlock Dispensary.—Resident Medical Officer, unmarried. Salary £120 per annum, with rooms and attendance.

Manchester Workhouse, Crumpsall.—Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, washing, and attendance

Northampton General Hospital.—House Surgeon, unmarried. Salary £90 per annum, with apartments, board, washing, and attendance

Oldham Infirmary.—Junior House Surgeon. Salary £75 per annum, with board, residence, and washing.

Paddington Infirmary and Workhouse.—Medical Officer for six months. Salary at rate of £72 per annum, with board, lodging, and washing.

Peckham House, Peckham, S.E.—Second Assistant Medical Officer Salary £150 per annum.

Poplar Hospital for Accidents, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

Prince of Wales's General Hospital, Tottenham, N.—House Surgeon, House Physician, Junior House Surgeon, and Junior House Physician, all for six months Salary of two former at rate of £75 per annum, and of two latter at rate of £40 per annum, with residence, board, and laundry.

Royal London Ophthalmic Hospital, City-road, E.C.—Assistant Surgeon.

Royal Naval Medical Service.—Examination for 15 Commissions

Royal Waterloo Hospital for Children and Women, Waterloo Bridge-road, Lambeth, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—House Surgeon for six months. Salary £25, with board, residence, and laundry.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Clinical Assistants.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

Southampton, Royal South Hants and Southampton Hospital.—House Physician Salary £100 per annum, with rooms, board, and washing.

Swansea General and Eye Hospital.—House Physician. Salary £75 per annum.

Torquay, Torbay Hospital.—House Surgeon. Salary £100 per annum, with residence and board

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Physician to Out patients.

Wakefield, Clayton Hospital.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

West London Hospital, Hammersmith-road, W.—Physician. Also Assistant Physician.

Births, Marriages, and Deaths.

BIRTHS.

Morley.—On April 5th, at 29, Gower-street, Bedford-square, the wife of Arthur S. Morley, F R C S, of a daughter.

Smyth.—On March 30th, at Digby House, Melton Mowbray, the wife of James A. Smyth, M.B., of a son

MARRIAGES.

[illegible] at Christ Church, Turnham Green, [illegible] Dickey, M.R C S. Eng, L.R C P. [illegible] daughter of Mr. and Mrs. Charles [illegible]

DEATHS.

Geoghegan.—On April 2nd, after a long illness, Alfred Osmond Geoghegan, M.D, Lieutenant-Colonel, R.A.M C (retired), in his 53rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SOME CHEMICAL REASONS FOR DETERIORATION IN LIQUID MEDICINES.

IN *Merck's Report* for March Mr. Frederic E. Niece calls attention to a number of chemical substances which do not keep well in solution. Chloroform water readily decomposes under the influence of heat, light, and air with the formation of acid by-products and the development of odours resembling those of phosphoretted hydrogen or decomposed marine algæ. The addition of 4 per cent. of alcohol is sufficient to keep this preparation indefinitely. Solutions of iodoform in chloroform are less stable than alcoholic solutions, because chloroform acts as a carrier of oxygen which liberates iodine in the solution under the influence of sunlight. Chloroform itself is decomposed in the presence of iodoform and the by-products tend to react with the iodine. Solutions of potassium iodide show the presence of free iodine within a very short time and afterwards potassium iodate, and so become a source of trouble from incompatibility and by producing unpleasant symptoms after administration. These changes may be retarded by keeping the solution in a cool, dark place, in full bottles, and by adding 0·2 per cent. of sodium thiosulphate. Ammonium iodide likewise readily forms free iodine when kept in solution, but the change may be lessened or prevented by the addition of a few drops of diluted ammonia. The decomposition of solutions of sodium hypobromite is a constant source of annoyance to many practitioners, owing to the deeper colour and loss in strength produced by the solution of traces of manganates from amber bottles. To prevent this change it is advisable to store the solution in green, blue, flint, or paraffin bottles with the addition of 10 per cent. of potassium bromide. The red colour produced in solutions of salts of eserine is caused by the combined action of light, atmospheric oxygen, and alkali present in the glass. This difficulty may be partially, if not completely, overcome by keeping the solution, prepared with sterile distilled water, in the dark in bottles coated on the inside with paraffin wax. As a further precaution Mr. Niece recommends the practice of covering the solution with a layer of washed and boiled liquid paraffin. This method is generally applicable in the case of sensitive and costly chemical substances which it is desired to keep in solution. [illegible] to withdraw the solution from beneath the paraffin layer it is necessary to use a pipette, and since a solution of eserine is generally used for eye lesions the presence of a trace of oil is not objectionable. Solutions of lead acetate form heavy white precipitates of lead carbonate on exposure, unless restrained by the presence of a trace of acetic acid. These illustrations serve to show the dangers that may lurk in bottles of solutions and stock mixtures which have been kept for some time.

A SUGGESTION FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—In reference to the treatment of the case mentioned by your correspondent "Perplexed" in THE LANCET of Feb. 20th, p. 589, allow me to suggest that he try ovarian extract. He states that the attacks seemingly have nothing to do with the menstrual period, but ovulation does not necessarily occur simultaneously with menstruation, and taking into consideration the age of the patient, I imagine that the headaches may be due to the approaching menopause. In two cases presenting somewhat similar symptoms I have been able to give relief by administering ovarian extract in five-grain doses three times a day for about a week at a time. Sometimes it was necessary to give it for a longer period, but I allowed myself to be guided by the symptoms.

A young woman, aged 26 years, on whom a panhysterectomy had been performed, consulted me complaining of severe headache. She had been treated by several practitioners, including an ophthalmologist, and had been given all kinds of treatment, including morphine, but without any permanent relief. I prescribed ovarian extract and the headaches became progressively less severe. Instead of being confined to bed for one week out of every month she gradually improved till by taking the remedy for a day or two she could avert an attack. The attacks in this case were preceded by "nervous" symptoms such as frequently usher in a menstrual period. I believe that the headache was due to loss of the internal secretion of the ovaries, and in my opinion in many cases the headaches occurring at the menopause are due to the same cause. I trust that this may be of service to "Perplexed."

I am, Sir, yours faithfully,

M.D.

Chicago, U.S.A., March 15th, 1909.

ACCIDENTS TO RAILWAY SERVANTS.

WE have received from Mr. T. A. Brockelbank a copy of a pamphlet dealing with a large number of accidents occurring among railway servants and advocating the adoption by English railways of automatic couplings. The figures in the pamphlet are very impressive and bring before us well the risks which have to be run by the employees of railways.

WE have had forwarded to us a metal "school box" for the use of children. It is a flat box made of tinned iron, and measuring 9½ inches by 2 inches by ½ inch. Inside are metal partitions which divide it into convenient spaces for pen, pencil, and ruler. The box, which is made by the South Wales Canister Company, is stamped with the name, "Cymric Aseptic School Box." It could undoubtedly be made aseptic by boiling, but we fear that its normal contents will hardly be aseptic when in use. We would also suggest that if the "tin" edges of the box should damage the hands of its owner the advantage of its asepticity would very likely be counterbalanced by the complexion of the aforesaid hands. A wooden box, even though not aseptic, will to many seem preferable for the reception of the child's implements of learning as less likely to cause any abrasion.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—Arthur Whitfield, E. G. Graham Little): at 5 P.M.

Exhibition of Cases.

FRIDAY.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretary—Reginald Morton): at 8.30 P.M.

Dr. Sloan: Vulvo-vaginal Electrode for Ionic Medication.

Mr. T. J. Bokenham: Treatment of Hæmorrhoids by Zinc Mercury Ionisation.

Mr. N. S. Finzi: Treatment of Ulcers by Ionic Medication.

Dr. Horace Manders will show an Apparatus for the Production of Continuous Oscillations.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Surgeon K. D. Bell, R.N.: Physical Training and the Medical Profession.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., Demonstration:—Dr. F. Thomson: Infectious Fevers (at the North-Eastern Fever Hospital, St. Ann's-road, N.).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X Rays. 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Operations (Mr. W. Edmunds). Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck-street, W.

MONDAY.—3 P.M., Clinical Demonstration: Dr. H. Campbell.

TUESDAY.—5 P.M., Clinical Demonstration: Dr. J. Mackenzie.

WEDNESDAY.—3 P.M., Clinical Demonstration: Dr. F. Palmer.

THURSDAY.—3 P.M., Clinical Demonstration: Dr. T. D. Savill.

FRIDAY.—2 P.M., Clinical Demonstration: Dr. P. Stewart. 5.30 P.M., Clinical Demonstration: Dr. E. Macnamara.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: Middle Ear and Labyrinth.

FRIDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: Middle Ear and Labyrinth.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Dr. L. Braddon (Seremban) and Dr. A. R. Wellington (Singapore): The Etiology of Beri-Beri.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	£	s.	d.
One Year	£1	12	6
Six Months	0	16	3
Three Months	0	8	2

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Sanitary Record, Liverpool Express, Weekly* [illegible] *Herald, Dublin Times, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. H. G. Adamson, Lond.; Ardath Tobacco Co., Lond.; Anglo-American Pharmaceutical Co., Croydon, Manager of; Messrs. R. Anderson and Co., Lond.; Dr. F. P. Atkinson, Bexhill-on-Sea; Army and Navy Male Nurses' Co-operation, Lond.; A. P. M.

B.—Dr. Carl Beck, New York; Dr. C. F [illegible]; Barebon [illegible] Hospital [illegible] Messrs. [illegible] and Co., [illegible] Paris; Bishopstone House, Bedford, Medical Superintendent of.

C.—Mr. R. E. Crosse, Lond.; Dr. H. Neville Crowe, Birmingham; Mr. Ernest P. Carmody, Tilehurst; Cumberland Infirmary, Carlisle, Secretary of; Clayton Hospital, Wakefield, Hon. Secretary of; The Commercial Publishers' Association, Lond., Secretary of; Continental Tyre and Rubber Co., Lond.; County Asylum, Rainhill, Clerk to the; Mr. F. W. Cory, Leeds.

D.—The Dominion Bank, Toronto, Assistant Manager of; Messrs. Duff, Morgan, and Vermont, Lond.; Messrs. Down Bros, Lond.; Messrs. W. Duff and Co., Lond.

E.—The Equitable Life Assurance Society, Lond., Secretary of; The Eccles and Patricroft Hospital, Hon. Secretary of; Dr. A. M. Elliot, Clacton-on-Sea.

F.—Folkestone, Town Clerk of; Dr. E. J. Foster, Fordwich, Canada; Mr. A. Fleming, Lond.

G.—Mr. C. H. Garland, Lond.; Messrs. F. Green and Co., Lond.; Dr. V. R. Goraksbakar, Hyderabad; General Practitioner; Mr. B. Grellier, Lond.; Dr. J. A. Gentle, Lond.

H.—Mr. H. H. Hillman, Lond.; Haywood Hospital, Burslem, Secretary of; H. D. M.; Dr. R. M. Hall, Stockbridge; Mr. H. Hamilton, Lond.

I.—The India Rubber, Gutta Percha and Telegraph Works, Co., Lond.

J.—Mr. G. P. *Jackson*, *Lond.*; Mr. J. Arnold Jones, Manchester.

K.—Messrs. Kutnow and Co., Lond.; Mr. R. C. B. Kerin, Lond.; Kettering and District General Hospital, Secretary of; K. L. S.; Dr. A. M. Kennedy, Glasgow.

L.—Mr. H. K. Lewis, Lond.; Dr. J. Littleton Lawry, Calstock; [illegible]

M.—Mr. C. A. Morton, Clifton; Mr. C. Mansell Moullin, Lond.; Messrs. C. Mitchell and Co., Lond.; Messrs. Mayer and Meltzer, Lond.; Mr. H. B. Mylvaganam, Bangalore; Messrs. Merttens and Co., Manchester; Dr. John Marnoch, Aberdeen; Mr. G. Murray, New York; Mr. J. M. MacLeod, Glasgow; Dr. W. F. Moore, Preston; *Midland Counties Herald*, Birmingham, Manager of.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.

O.—Mr. F. W. Ord, Castle Gresley; Messrs. Osborne-Peacock Co., Manchester.

P.—Dr. F. C. Pybus, Lond.; [illegible] tenham, Director of; Dr. C. E. Purslow, [illegible] House, [illegible] Dr. J. [illegible] Dr. John Phillips, Lond.

R.—Mr. Clifford Robinson, Southport; Ruskin College, Oxford, Hon. Secretary to the Executive Committee; Royal Waterloo Hospital for Children and Women, Lond., Secretary of; Royal Society of Medicine, Lond., Secretary of; Royal South Hants and Southampton Hospital, Secretary of; Royal London Ophthalmic Hospital, Secretary of; Royal Infirmary, Hull, Secretary of; Rotherham Hospital, Secretary of.

S.—Mr. F. Spencer, Tavistock; Messrs. W. H. Smith and Son, Lond.; Mr. T. Shore, Farnham; Star [illegible] hampt [illegible] Hospi [illegible] William G. Shipwright, Lond.; Mr. S. K. Senguptu, Calcutta; Scholastic, Clerical, &c., Association, Lond., Secretary of; Messrs. R. Sumner and Co., Liverpool; Saarbach's News Exchange, Mainz; *South Wales Argus*, Newport, Manager of; Salter Typewriter Co., West Bromwich; Dr. E. M. Spencer, Tavistock; Dr. G. I. T. Stewart, Ipswich.

T.—Mr. T. *Tulloch*, *Lond.*; Messrs. Thrupp and Maberly, Lond.; Lieutenant R. G. H. Tate, R.A.M.C., Amballa; Torbay Hospital, Torquay, Secretary of; Toronto University, Librarian of Medical Department; T. B.

U.—Union Rěklamě, Lucerne.

V.—Messrs. Van Alexander and Co, Lond.

W.—Mr. G. *Whittington*, Rouen; Mr. W. A. Winship, San Diego; Messrs. W. Wood and Co., New York; The West Disinfecting Co., New York; *Wimbledon Borough News*, Editor of; Dr. B. Ward, Llanelly.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. F. C. Angear, Chatham; A. H. W.

B.—Mr. T. B. Browne, Lond.; Mr. G. W. J. Baker, Stourbridge; Mr. H. [illegible] ton; Mr [illegible] Mr. C. S. [illegible] Sir J. C [illegible] fries; Brislington House, Bristol, Steward of; Dr. D. Birt, Wakefield; Beckett Hospital, Barnsley, Hon. Secretary of.

C.—Mr. Harrison Cripps, Lond.; Messrs. Cook and Wylie, Stirling; Cambridgeshire County Council, Cambridge, Clerk to the; C. C. S.; Messrs. T. Colman and Co., Lond.; Messrs. T. Christy and Co., Lond.; Mr. R. A. Cameron, Cathcart, Cape Colony; C. B. H.; Messrs. Crossley and Co., Lond.; Messrs. Clarke, Son, and Platt, Lond.; C. D. T.

D.—Dr. G. B. S. Darter, Victoria West; Mr. F. Diemer, Cairo; D. W.

E.—Mr. W. L. Edwards, Barry; Mr. J. W. Elliott, Bournemouth.

F.—Dr. J. M. Fortescue-Brickdale, Bristol; Messrs. Frowde, Hodder, and Stoughton, Lond.; Messrs. Ferris and Co., Bristol.

G.—Dr. E. W. Ginner, Cannes; Dr. J. A. Glover, Lond.; Dr. O. F. F. Grunbaum, Lond.

H.—[illegible] Dr. [illegible] Ma [illegible] Roche Chemical Works, Lond.; Dr. R. Hamilton, Broughton-in-Furness; Mr. W. Hart, Lond.

I.—Inverness District Asylum, Clerk to the; International Plasmon, Lond.

J.—Dr. R. W. Jones, Penrhiwceiber; J. W. N.; J. C. J.; J. H.; J. G. B.

K.—Mr. W. H. King, High Barnet; Messrs. C. Knight and Co, Lond.; Mr. F. King, Lond.

L.—Mr. J. Lacayo, Manchester; "Locum," Sunderland.

M.—Dr. P. Modlinski, Moscow; Mr. W. G. R. Macauley, Lond.; Dr. G. A. Mason, Lond.; Messrs. Muller, Maclean and Co., Lond.; Dr. D. J. Marr, Nottingham; Mr. R. Mosse, Berlin; Messrs. May, Roberts, and Co., Lond.; Mr. A. S. *Morley*, *Lond.*; Mr. R. Morison, Newcastle-on-Tyne.

N.—Mr. S. Neave, Ingatestone; Messrs. Nicolay and Co., Lond.; Messrs. T. Nelson and Co., Manchester.

O.—Dr. S. Oliva, Gibraltar; O. S.

P.—Mr. F. D. Potter, Lond.; Messrs. Pratt and Co., Manchester; Porbander State, Kathiawar, India, Chief Medical Officer of; Mr. C. R. Porter, *Berkhampstead*; *The Prescriber*, Edinburgh, Manager of; Dr. E. J. Parry, Pontycymmer.

R.—Dr. T. W. Reid, Canterbury; Messrs. E. J. Reid and Co, Lond.; Mr. P. Ruat, Marseilles; R. H. D. W.

S.—Dr. J. A. Struthers, Carlisle; Dr. C. E. de Silva, Galle; Mr. C. F. Scripps, Lond.; S. W.; Messrs. Spiers and Pond, Lond.

T.—T. M.; T. W. T.

V.—Messrs. Van Houten, *Lond*; Messrs. G. Van Abbott and Sons, Lond.

W.—Mr. B. Williams, Prestatyn; Mr. A. H. Wade, Milford Haven; Dr. W. D. Wilkins, Benenden; Messrs. F. Williams and Co, Lond.; Mr. R. Walker, Aberdeen; Mr. R. S. Wright, Ashby-de-la-Zouch; Dr. W. Wright, *Lond*; Lieutenant-Colonel J. H. T. Walsh, I.M.S., Norwich; Mr. J. Ward, Lond.; W. L; West Suffolk General Hospital, Bury St. Edmund's, Secretary of.

An original and novel feature of "THE LANCET General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be *delivered at the Office* not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

The Goulstonian Lectures

ON

SOME DISORDERS OF THE CEREBRAL CIRCULATION AND THEIR CLINICAL MANIFESTATIONS.

Delivered before the Royal College of Physicians of London on March 11th, 16th, and 18th, 1909,

BY ALFRED E. RUSSELL, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

LECTURE III.[1]

Delivered on March 18th.

MR. PRESIDENT AND GENTLEMEN,—Finally, the subject has been studied experimentally by various observers. The blood-supply to the brain of animals has been cut off and the effects produced on allowing the circulation to return have been studied. One of the most exhaustive studies has been made by Messrs. Stewart, Guthrie, Burns, and Pike.[2] Their experiments were performed on cats. The animals were anæsthetised with ether. Ligatures were placed round the innominate and the left subclavian artery proximal to the origin of the vertebral artery, the blood-flow being stopped by traction on the ligatures. Artificial respiration was kept up. There is, however, an important distinction between their experiments and the results obtaining in the cases here described. In the experiments the blood flow was cut off from the brain and medulla only, the circulation in the greater part of the cord and in the trunk and lower extremities remaining, whereas in the cases described in the last lecture the whole circulation of necessity came to an end.

Muscular movements.—There was usually a sudden stiffening of all the muscles following occlusion, with violent movements of fore and hind limbs and tail. Micturition and defæcation might occur. Then the fore-limb movements ceased, shortly afterwards the hind limbs relaxed and the whole animal lay limp and quiet until after the restoration of the cerebral circulation. The cerebral circulation was allowed to return after varying periods and the effects were noted.

Respiration.—The first sign of returning vitality in the respiratory centre was a strong gasp. This was repeated at progressively shorter intervals until spontaneous breathing was established. The first gasp might occur at a long interval after the restoration of the circulation. Thus, after an occlusion of 28 minutes the first gasp occurred 40 minutes after release.

Convulsions.—Convulsions varying in severity from occasional twitchings of the limbs to extreme opisthotonos and violent struggles of tonic or clonic type sometimes begin before the full return of the reflexes. Occasionally the cat may lie quiet for one to three hours before the convulsions begin. The head may be drawn back in extreme opisthotonos or may be bent downwards with the back convex. There may be tonic spasm of the fore limbs and clonic spasms of the hind limbs. Again, there may be violent clonic spasms in which the animal flings itself about from one side of the room to the other. The convulsions may follow in such rapid succession as to make it difficult to distinguish any interval between successive seizures.

THE TIME LIMIT OF THE RECOVERY OF THE BRAIN FROM ARREST OF THE CIRCULATION.

In the experiments on cats no animal recovered after a longer period of occlusion than 16½ minutes, though in one case after 22 minutes' occlusion the animal recovered without loss of intelligence but with paralysis of one fore limb, death following, however, from pneumonia on the seventh day. But these experiments did not impose so severe a test as in cardiac inhibition in man, for the heart remained beating during the whole period of occlusion of the cerebral arteries, so that the life of the spinal cord and of the rest of the body was not interfered with. The integrity of the spinal cord was found to be essential to recovery, transection in the upper dorsal region being incompatible with the resuscitation of the cerebral centres. In the cases recorded in man the spinal cord suffered from the same arrest of blood-supply as the brain, and though this might not be so severe an injury as transection it would presumably materially diminish the chances of recovery. It is difficult to say for what period the brain can withstand the total arrest of its blood-supply and the patient make a complete recovery. In one case of chloroform syncope the heart appeared to be completely arrested for seven or eight minutes before direct cardiac massage was commenced. A disaster such as chloroform syncope is not conducive to accurate observations of time, and it is probable that the heart gave some beats under the artificial respiration, &c., applied during this period, but it was motionless when massage was begun and five minutes elapsed before its contractility was restored. Some blood would presumably be forced round the circulatory system during this five minutes, so that the full five minutes could not be added to the seven or eight. We are probably safe in assuming that about five minutes' loss of its circulation is the outside limit of time that the brain can withstand and recover completely. The heart itself, even in man, can, of course, withstand much longer periods of arrest and recover its contractility.

THE CONDITION OF THE BRAIN.

In the clinical cases no evidence of gross lesion of the brain was found post mortem and the cause of the non-recovery of the cerebral functions must be sought in some change affecting the nutrition of the neuron. Œdema of the brain was not noted as being present in either of the two cases which I reported, indeed in one the ventricles were described as not containing any excess of fluid and in the other the brain tissue was noted as being fairly firm. Convulsive seizures are a noticeable feature in these cases and would raise the intracranial pressure, a condition probably favourable to the passage of blood from the cerebral capillaries into the perivascular spaces. Until further knowledge of the histological changes in the brain in these cases is forthcoming, the cause of the non-recovery must be attributed to injury to the neurons and possibly to cerebral œdema.

REVIEW OF THE SYMPTOMS.

The cases come under very different categories: first, sudden cardiac inhibition during puncture of the chest or lavage of the pleura; secondly, cardiac inhibition in patients already unconscious from the influence of chloroform; and thirdly, experiments on animals in which no cardiac inhibition occurs, the supply of blood to the brain alone being abolished.

In the first group the inhibition may be of varying degrees of intensity and duration. (*a*) Sudden severe fatal syncope. Numerous cases as noted are on record. (*b*) Sudden syncope followed by complete recovery after the most alarming symptoms. (*c*) Sudden syncope; partial recovery, followed by death after varying periods of time; this class may be compared with the cases occurring under chloroform anæsthesia in which the onset of symptoms is denoted by arrest of pulse and respiration, but with the resuscitation of the heart and with the disappearance of the effects of the anæsthetic these cases are identical save for the extra shock attending the surgical operation. It is also comparable to a considerable extent with the third group—the animals whose cerebral vessels were ligatured for varying times, save that in these the circulation through the rest of the body was maintained.

The onset.—The suddenness of onset is highly characteristic [illegible] uncon-

[illegible] e wrist, in others it has been noted as feeble or slow or intermittent.

Spasms.—(*a*) Initial tonic spasm. In the case of sudden death I reported tonic extensor spasm of arms was noted, with a convergent squint. In other cases sudden tonic spasm has been noted. This initial spasm is to be distinguished from the later convulsive movements and would appear to be the direct result of the sudden cessation of the cerebral circulation. It probably occurs oftener than is recorded, as the extreme urgency of the cardiac failure in these cases is not conducive to observations of transient symptoms. In the cases of chloroform syncope the anæsthetic would doubtless negative the spasm. In the experiments on cats "there was usually a sudden stiffening of all the muscles following occlusion, with violent movements of fore and hind limbs and tail. .. .. Then the fore-limb movements ceased, shortly afterwards the hind limbs relaxed, and the whole animal lay limp and quiet until after the restoration of the cerebral circulation." The sudden stiffening is obviously the same phenomenon as the initial tonic spasm in man; the violent movements of limbs and tail might depend on the fact that the spinal circulation was intact in the animals. (Leonard Hill noted the frequency of extensor rigidity when the limit of cerebral anæmia is reached and the excitability of the cortex is vanishing.) This initial spasm is seen in the tonic spasm observed after the unconsciousness and fall of the epileptic fit. (*b*) Clonic convulsions. These do not seem to occur in the cases of sudden and permanent cardiac inhibition. In the two cases I have seen, in the one with sudden death only extensor tonic spasm of arms was observed; in another which occurred when I was syringing out the pleural cavity the patient, who was sitting up in bed, fell backwards with absolute suddenness. There certainly were no clonic convulsions and I do not remember whether any tonic spasm occurred. Clonic convulsions in these cases appear to be conditioned by the return of the cerebral circulation. Their time of onset varies very considerably. They may appear very soon after the onset of syncope, or they may appear much later, as in the case of the child at St. Thomas's Hospital, in whom the first fit occurred two hours after the attack. Considerable variation was also noticed in the experiments on cats, in whom the convulsions might appear speedily after the release of the vessels from occlusion or not for an hour or more. With a very long period of complete cerebral anæmia the functions of the cortex and tracts must be permanently abolished With periods of anæmia shorter than this the excitability of the cortex and the conductivity of the tracts revive on restoration of the circulation. Leonard Hill's researches prove that a stage of hyper-excitability precedes paralysis when the cortex is rendered anæmic.

---

[1] Lectures I. and II. were published in THE LANCET of April 3rd [illegible]

[2] [illegible] us System of Mammals, by [illegible] and F. H. Pike, Journal of [illegible] 9.

Subsequent course of these cases.—In addition to the symptoms already mentioned the pupils dilate and become insensitive to light. Involuntary micturition and defæcation occur. Severe perspirations are common. Consciousness does not return, convulsions may recur from time to time, the deep reflexes may be exaggerated, irregular movements or rigidity of one limb or of both limbs of one side may occur, hemianæsthesia may be detectable, and finally death occurs. In one case here recorded death did not occur till the fifth day. In the case of the cats definite dementia was noted, in some cases following long occlusion of vessels. A similar condition has been observed by Leonard Hill in dogs and monkeys.

These cases of sudden failure of the cerebral circulation, whether produced by cardiac inhibition following pleural or pulmonary stimulation, or by sudden chloroform syncope, or by experimental ligation of cerebral arteries, are of great importance, not merely in that the clinical symptoms are of profound interest, but in view of the gravity of these accidents. They have also, I think, some bearing on the phenomena of epilepsy. Following upon a sudden arrest of the circulation, sudden syncope with unconsciousness is produced. In several cases transient tonic spasm was observed, and it may be that this is a common symptom. The first two symptoms of an epileptic fit are thus reproduced. Inasmuch as the arrest of the cerebral circulation in the cases just described was of very considerable duration, so long, in fact, as to render recovery impossible, the subsequent symptoms of necessity differ from those of the transient epileptic fit. Clonic convulsions do, however, occur with the return of the circulation. The condition bears some resemblance to status epilepticus and a stronger resemblance to some cases of uræmia. It is unquestionably the result of the severe cerebral anæmia, and in the next section evidence will be given that both status epilepticus and uræmic coma and convulsions also depend upon the same factor.

ON DIMINUTION IN THE BLOOD FLOW THROUGH THE BRAIN AS THE RESULT OF INCREASED INTRACRANIAL TENSION.

The experimental results following increased intracranial tension have been studied by Harvey Cushing.[3] He showed that if the intracranial pressure be rapidly increased "Kussmaul-Tenner spasms, evacuation of bladder and rectum, practical cessation of respiration, and pronounced vagus effect upon the heart, often with a complete standstill, lasting from 10 to 20 seconds, may develop. Then follows a release from this extreme vagus inhibition and the vasomotor centre exerts its influence." With a slower increase of the intracranial pressure a different series of events occurred. The pressure against the brain could be increased to the point of its equalling the blood pressure before any symptoms referable to the centres in the medulla were called forth. Direct examination of the cortex through a circular disc of glass fitting tightly into a second trephine hole showed at this period of equalisation of blood pressure and intracranial tension an *abrupt blanching* of the exposed convolutions. The pulsating arteries could be seen against the blanched background and the dark blue veins in the sulci remained filled with blood, but presumably little, if any, circulation passed between them The usual consequence was not death *but a stimulation of the vaso-motor centre, which occasioned a rise in blood pressure sufficient to overcome the high intracranial tension;* the cerebral circulation was re-established and the rosy colour could be seen through the glass window in the trephine hole to return again to the blanched convolution. With further increase in intracranial tension the blood pressure rose *pari passu* and always to a point exceeding the intracranial tension. This process could be repeated until the arterial pressure was forced to two or three times its normal level, sometimes to as much as 250 mm. Hg, without evidence of vaso-motor failure. By this mechanism the vital centres in the medulla and the life of the brain and entire animal are protected.

Clinically it is well established that many of the symptoms of cerebral tumour, hydrocephalus, cerebral hæmorrhage, &c., are dependent upon an increase of the intracranial tension. Among such symptoms may be mentioned headache, vomiting, coma, convulsions, choked disc, &c. Extraordinary relief to these symptoms is attained after the pressure is relieved by surgical intervention. An admirable series of cases has been recorded by Harvey Cushing. The clinical evidence as obtained, therefore, from cases of cerebral tumour, cerebral hæmorrhage, &c., is in complete accord with the conclusions arrived at experimentally by Harvey Cushing. To recapitulate, it is clear that a rise in intracranial tension produced by the introduction of any foreign element, such as a tumour mass, blood, &c., must tend to diminish the blood flow through the brain. As the tension increases a point would be reached at which the intracranial tension equals that of the general blood pressure The cerebral circulation would, therefore, cease were it not that by a compensatory process the general blood pressure rises to a point above that of the intracranial pressure, and thereby maintains the flow of blood through the brain. But with a great increase of intracranial tension certain general effects are produced, apart from focal symptoms, dependent upon the position of the lesion. Headache, for instance, is common and is probably attributable to tension of dura mater and tentorial structures.

Optic neuritis is to be attributed, in the main, to a passive venous congestion of the retinal veins, and subsides or improves on relief of intracranial tension, sometimes with extraordinary rapidity.

Finally, coma is almost invariable in the last stages of cerebral tumour and in large cerebral hæmorrhages. Convulsions are also frequent in these conditions. Both are remarkably improved by methods capable of lowering the cerebral pressure, such as trephining or lumbar puncture And it is to be noted that by lowering the intracranial tension a free access of blood to the brain is facilitated.

Uræmia.—Uræmic convulsions may be absolutely indistinguishable from those of idiopathic epilepsy, and if it can be shown that there is evidence of a condition of cerebral anæmia in uræmia, support would be lent to the similar theory as applied to epilepsy. In a paper read before the West London Medico-Chirurgical Society I brought forward evidence to show that the cerebral manifestations of uræmia are due to cerebral anæmia produced by an increase of intracranial tension, resulting in all probability from cerebral œdema.[4] In the cerebral manifestations of uræmia we frequently see a symptom-complex almost identical with that of cerebral compression—viz., headache, vomiting, drowsiness, coma, convulsions, optic neuritis, &c. This symptom-complex is, at any rate in great measure, dependent upon increased intracranial tension, for many cases are now on record in which extraordinary relief has followed lumbar puncture, a procedure which, by means of allowing some of the fluid to escape, diminishes the pressure within the cerebro-spinal space. Numerous cases of uræmia were quoted from the literature in which marked relief had followed on the lowering of intracranial tension by means of removal of cerebro-spinal fluid by lumbar puncture. It is well known that uræmic convulsions and [illegible] such treatment, but the prom[illegible]ment occurred was such as to leave no doubt in the minds of the observers that the relation was one of cause and effect. It is noteworthy also that in most of the cases the cerebro-spinal fluid did escape under considerable pressure.

---

[3] Some Experimental and Clinical Observations concerning States of Increased Intracranial Tension, American Journal of the Medical Sciences, 1902, vol. cxxiv., p. 375.

[4] Uræmia, West London Medical Journal, 1907, vol. xii., p 9.

But relief has not always attended the performance of lumbar puncture in uræmia, and this may be due to the fact that this operation can only relieve intracranial pressure by removal of the *free* cerebro-spinal fluid. If, however, the pressure is mainly produced by a cerebral œdema, then, unless a co-existent excess of free ventricular fluid were present, the removal of the little that would flow might not be sufficient to relieve the pressure materially.

The manifestations of uræmia here considered, which are so strikingly relieved by lumbar puncture, are, as has been pointed out, so closely similar to the pressure symptoms produced in other conditions—such as cerebral tumour, cerebral hæmorrhage, &c.—that uræmia has not infrequently been erroneously diagnosed as cerebral tumour, and the fact that the cerebro-spinal fluid is often under considerable pressure in these cases of uræmia indicates that the underlying condition of increased intracranial tension must be responsible for the symptoms. Harvey Cushing, indeed, makes this suggestion in the paper on the establishment of cerebral hernia above referred to: "I have come to believe that the same causes must underlie the choked disc of tumour and the so-called retinitis associated with renal disease. It seems not improbable that an increase of intracranial tension due to cerebral œdema may be responsible for the occasional retinal changes in Bright's disease, as well as for the headache and vomiting which may characterise it." The correctness of Cushing's views, founded on a series of brilliant researches, both experimental and clinical, is still further supported by a recent account of a case of uræmia in which subtemporal decompression was attended with most successful results.[5] The authors' conclusions were that the neuro-retinal and cerebral manifestations of uræmia are due to œdema of the brain, and also the local and transient hemiplegias, aphasias, amauroses, Jacksonian fits, &c.

Uræmic coma.—The foregoing facts indicate that in uræmia a state of increased intracranial tension is present and that relief of pressure by lumbar puncture or decompression causes a marked alleviation of the symptoms. Traube's view that cerebral œdema (which would produce the rise in the intracranial tension) produces anæmia of the brain is strongly supported by the above facts and especially by the striking case of decompression. The late Dr. Beevor also remarked, when injecting brains of people dead from various causes, that "it was particularly observed that the cases, where the injection did not penetrate well, were those suffering from granular nephritis or alcoholism, where there was much fluid in the subarachnoid space of the brain."[6] Concurrently with the increase of intracranial tension the blood pressure rises and we see the slow tense pulse so common in uræmia. This conservative rise of blood pressure maintains the cerebral circulation. If the tension progressively rises the compensatory rise of blood pressure cannot go on indefinitely, and a point may be reached beyond which no amount of vaso-constriction and cardiac augmentation can maintain an adequate cerebral circulation. If this point is reached gradually and the volume of blood passing through the brain be slowly diminished, we should expect a comatose condition to develop, the last stage of cerebral compression with gradual respiratory failure, the high-tension slow pulse of the early stage of compression changing into a soft, rapid pulse, with the developing vaso-motor failure. A concomitant toxic action on the brain is not denied; such may be present and aid in the production of the cerebral symptoms. But the anæmia alone should suffice to induce the coma.

Uræmic convulsions.—Under the severe strain imposed upon it in working against this conservative high blood pressure the heart may fail rapidly in chronic nephritis. Should this occur, or should the vaso-motor centre fail rapidly, it is clear that the cerebral circulation must fail equally rapidly when [illegible] high. Instead of [illegible] developing into coma [illegible] result, and convulsions would readily be produced. It is of great interest to note that the onset of uræmic convulsions is, in fact, very apt to be associated with marked evidences of circulatory failure.

In cases of acute uræmia in acute nephritis it is well known that an increase of blood pressure is common, and the cardiac failure may be more readily induced owing to the more toxic character of some of the diseases associated with acute nephritis, the poisons of the acute infections, such as scarlet fever, materially affecting the heart muscle. The heart would thereby be unable to respond to the vaso-constriction above described, and the conservative rise of blood pressure would fail to develop.

In conclusion, it is submitted that the pathology of the cerebral manifestations of uræmia is to be sought in a condition of œdema and increased intracranial tension with failure of the cerebral circulation produced in the manner suggested; a gradual failure producing coma, a rapid one convulsions. If this conclusion be correct, strong support is lent to the theory that the fits of idiopathic epilepsy are produced by sudden failures in the cerebral circulation, for it is notorious that the convulsions of uræmia and of idiopathic epilepsy may be absolutely indistinguishable, and it is extremely probable that the factor underlying conditions so remarkable and so identical should be one and the same.

Status epilepticus.—Morgan Hodskins and Arthur Morton have reported a series of seven cases of status epilepticus treated by lumbar puncture. It is noteworthy that in four out of the seven cases recovery ensued, and that in every case but one there was an immediate and marked improvement as the result of the lumbar puncture. Further, in six of the cases the cerebro-spinal fluid was evidently under increased pressure, and in the only case in which the blood pressure was estimated it fell from 140 millimetres of mercury to 127 millimetres as the result of the puncture. Other successful cases are on record. These facts suggest that the condition of status is similar to what is seen in uræmia, in which, as has been pointed out, there is an increase of the cerebro-spinal pressure. And this increased pressure would tend to produce an anæmia of the brain unless the blood pressure rose to a point higher than that obtaining within the cranial cavity. The inference, therefore, that status epilepticus is due to anæmia of the brain brought about by increased intracranial tension does not appear unreasonable. It is possible that an unduly severe and prolonged fit in some way evokes œdema of the brain and that the increased pressure resulting from this is responsible for the anæmia and the continuance of the fits.

Mott[7] has shown that the essential changes in the brain in cases of status epilepticus are: "1. Great venous congestion and stasis. 2. *Œdema of the brain* and marked distension of the perivascular lymphatics, flattening of the convolutions, and naked-eye increased vascularity; but inasmuch as the brain is contained in a closed [illegible] must be associated with a [illegible] *anæmia.*" It is interesting al[illegible] experimental ligature of arteries in animals leads not only to anæmia of the brain but also to œdema. Continuing the above quotation: "In the case of experimental ligation of arteries in animals, the effect may be similar but it is brought about by an entirely converse process. The œdema of the brain and venous stasis are here proportional to, and determined by, the diminution of arterial blood in the arterio-capillary systems. ...... Microscopical observations show that the whole brain is permeated by a canalicular lymph system containing cerebro-spinal fluid, the large processes of the neurons lying in lymph spaces which are continuous with the perivascular lymphatics. These perineuronal spaces were very obvious in some of the cases of experimental anæmia." In this connexion it is a striking fact that, in his description of the photo-micrographs accompanying his paper, Mott comments on the close similarity between the appearance of the brain cells and perineuronal spaces in experimental anæmia of the brain (by ligature) and in status epilepticus.

[6] C. E. Beevor: On the Distribution of the Different Arteries Supplying the Human Brain, Philosophical Transactions of the Royal Society, 1908, Series B, vol. cc., p 15.

[7] [illegible] p. 499.

These observations, both clinical and pathological, lead to the conclusion that the fundamental condition underlying the condition of status epilepticus is cerebral anæmia. It might be urged that, inasmuch as it is not probable that there is a great rise of cerebral pressure, the heart should be able to respond by more powerful contractions which would maintain the cerebral circulation (*vide* Harvey Cushing's observations). It is interesting to note in this connexion that the heart in cases of status epilepticus shows extreme fatty degeneration; thus Mott[8] has shown that "the œdema of the muscle substance of the heart is very striking upon microscopical examination; networks of capillaries are seen, small hæmorrhages are sometimes observed, and the fibres are separated from one another by a serous exudation. This of itself would embarrass the much over-worked organ; but the lymph around the muscle fibres no longer constitutes a normal environment, it contains excess of carbonic acid, deficient oxygen, and toxic fatigue products, the result of excessive muscular activity and imperfect metabolism. The fibres thus imperfectly nourished and oxygenated are the seat of an imperfect metabolism which is manifested upon microscopical examination by a lustreless appearance, indistinctness of striation, and accumulation of minute particles of fat in the substance of the fibres. ...... In seven cases of status epilepticus, and in a large number of cases of general paralysis dying after prolonged convulsive seizures, I have invariably found this fatty change in the heart and striated muscles."

THE EPILEPTIFORM SEIZURES OF GENERAL PARALYSIS.

Mott has shown that "œdema of the brain, owing to dilatation of the perivascular lymphatics, is a striking feature in general paralysis, and the water which can be extracted from the brain by placing it in a desiccator is larger in amount than in the normal brain. But venous congestion and œdema of the brain must be associated with arterial anæmia. ...... If all the arteries to a dog's brain be ligatured there is established an arterial anæmia, but the veins of the cortex will be found greatly congested, the perivascular lymphatics distended, and the motor cortex excitable, even hyper-excitable, to electric stimulation. This makes it probable that the epileptiform seizures of general paralysis are associated with, and probably dependent upon, venous congestions and stasis, arterial anæmia and increased excitability."

THE RÔLE OF THE SALIVA IN THE TRANSMISSION OF TUBERCLE.

BY NEWMAN NEILD, M.B., CH.B. VICT., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL;
LECTURER ON PHARMACOLOGY AND THERAPEUTICS,
UNIVERSITY COLLEGE, BRISTOL;
AND
E. V. DUNKLEY, M.B., B.S. LOND.,
LATE PATHOLOGIST TO THE BRISTOL GENERAL HOSPITAL.

TO prevent the transmission of the tubercle bacillus from the tuberculous to the non-tuberculous and to maintain the general health of the non-tuberculous are the main principles in the prophylaxis of tuberculosis.

The danger of sputum as a carrier of tubercle bacilli is fully recognised and every case under proper treatment is educated in the care of the sputum. But we have been struck by the freedom with which the tuberculous use their saliva for purposes in no way connected with the digestion, and also by the fact that few, if any, tuberculous patients are warned against such uses. It is known that bacilli may be obtained from the mouth in the case of patients suffering from pulmonary tuberculosis, and it has even been recommended that mucus should be obtained from the larynx for examination in suspected cases where sputum is not available.

In order to find whether the saliva from the tongue was contaminated at all frequently by the tubercle bacillus we examined 50 cases of pulmonary tuberculosis, derived in part from amongst the out-patients of the Bristol General Hospital and in part from the Winsley Sanatorium. This series only included those cases in which the tubercle bacillus had been demonstrated in the sputum, cases, therefore, of open tuberculosis. The method adopted was to stroke the anterior part of the patient's tongue with the stick of a wooden match and apply the saliva obtained to an albuminised slide. The slide was then stained by the Ziehl-Neelsen method, each specimen being stained in separate bulk of stain, and all positives being examined by us both. In this way tubercle bacilli were demonstrated in 29 cases out of 50. Amongst the first 11 cases were three in which tubercle bacilli were not found in the saliva examined before expectoration, the bacilli only being found after an expectoration to order. Since the other 39 cases were examined with no regard to the time at which the patient expectorated or even coughed the first 11 cases will be brought into line if we consider these three as being negative, thereby reducing the number of positive cases to 26. It may be urged that many of these tubercle bacilli were innocuous but, on the other hand, inoculations, in all probability, would have demonstrated active bacilli where the Ziehl-Neelsen method of examination failed to demonstrate their presence and an even higher percentage of positives obtained. The average patient assumes, if indeed he thinks of it at all, that when he has expectorated the sputum the mouth remains untainted; he has been taught that the bacilli are in the sputum and he has flasked and pocketed the sputum. In cases in which the expectoration was recent the bacilli were found more frequently than in those cases in which it was not so recent. In some positive cases there had been no expectoration for an hour or more before the examination (e.g., Case 11, tubercle bacilli numerous; Case 15, tubercle bacilli scarce). In some instances where no expectoration had been noticed by the patient for some six or seven hours bacilli were found in the saliva (e.g., Case 9, few bacilli; Case 14, numerous bacilli). One patient in the sanatorium denied having had any cough or expectoration for many days, and yet a few bacilli were found (Case 13). On the other hand, where there was frequent profuse expectoration such as one may get from large cavities the bacilli might be scarce or even not found at all by this method of staining, a fact that will cause no surprise to those who have had some experience in the examination of sputum. We also noticed that specimens taken some hours after a meal were more likely to give a positive result than were those taken within an hour after a meal.

The uses to which the saliva is put are, unfortunately, numerous. To some of these we shall now refer. In this connexion some of the 50 cases are of interest.

Case 18.—The lead of a mechanical pencil was dropped on the floor of this patient's room. He kindly helped in the search, and being the first to catch sight of the object he licked his finger to assist adhesion and would have recovered the lead by that method had he not been prevented. An examination of his saliva was made. He admitted having an occasional cough, but stated that there had been no expectoration for a week or more. "Very numerous T.B." were found. He had just come in from the garden where he had been working with a rake, and we can only surmise the possibilities of the presence of "very numerous T.B." upon the handle of that implement.

Case 19.—A consumptive out-patient, placing his book before the physician, was about to turn the page with an adequately moistened finger when he was prevented. No examination was made at this time, but his name was found amongst those who had previously been examined with positive result.

Case 42.—Another consumptive out-patient with similar intentions had his saliva examined at once with positive result.

These three cases were of the labouring or mechanic class, so that one is not surprised at their use of saliva in operations requiring some delicacy of touch, bearing in mind the lavish way in which the hands are prepared for a firm grip of the handle of an implement. But this use of the saliva for turning over the leaves of a book is not absolutely confined to the more uneducated classes. The danger of this practice is no imaginary possibility, but is so widely known that finger-dampers are provided for the clerks in many offices to obviate the use of the saliva. A medical man when dealing with a case of tuberculosis in a clerk inquires as to the presence of other cases of tuberculosis in the office or after the health of the clerk whose books his patient may have taken over. *Moistening the fingers in order to obtain a firm grip* of an implement is not unknown amongst well-educated men when the implement in question is a cricket bat or a tennis racquet. And the use of a cricket bat is not always confined to the owner. The sempstress often applies her saliva to both ends of the thread, first to facilitate threading the needle and then to form a knot on the other end. The observant can hardly claim that this practice is limited to the poor. We do not wish for a moment to suggest that every garment made by a person with open tuberculosis must be a "shirt of Nessus" in its effect, but not all needlework is washed before it is first used, and slight though the danger may be from this disagreeable habit it is a danger that might well be avoided.

---

[8] Mott. Loc. cit., pp. 502, 503.

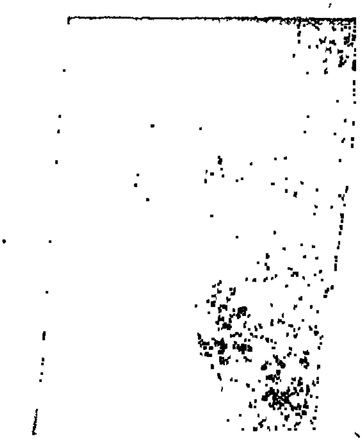
The commonest use of saliva amongst the educated is to close envelopes and stick stamps, so common, indeed, that it would seem almost hopeless to attack this method. An equally convenient and secure form of envelope that would not require the use of the saliva or a damper would be appreciated by all of us. It may be urged that this method of using the saliva is a fairly safe proceeding, since any tubercle bacilli applied to the gum are securely sealed down. But observe the process more closely and it will be seen that the *saliva often spreads beyond the gum or even the flap* of the envelope. Some people, having a fastidious objection to the flavour of gum, prefer to apply saliva to that part of the envelope to which the flap is to adhere; some lick the corner of the envelope and apply the stamp somewhere in this moistened area; others apply the stamp face downwards upon the tongue, leaving it there until the gummed side becomes soft. So much for the idea that all bacilli are sealed down. We obtained envelopes which had been sealed down by consumptives and, cutting out the gummed portions together with a broad margin, washed them and examined for tubercle bacilli the centrifugalised deposit from the washings. The specimens were stained by the Ziehl-Neelsen method as before. The first specimen yielded various bacilli from the mouth, leucocytes and squamous epithelium. The second specimen showed tubercle bacilli. Again, we do not wish to suggest that this method is a fertile source of infection, even where the receivers open such envelopes at the breakfast table with their fingers or a prong of a fork. But where a patient has been taught, and rightly so, to expectorate all sputum, and he sends a licked envelope two or three times a week to the same correspondent, it must be admitted that the receiver runs a risk which he might reasonably be spared. And yet one of us, from his experience in sanatoriums in this country and on the continent, believes that it is the exception for patients to be warned on this point.

The danger of the use of saliva for "rubbing out on a slate is so well known as to have helped in the abolition of slates from many schools. Children and some adults wet the point of lead pencils when they write with them, nor do *they object when others use these pencils, the borrowers* substituting their own saliva for that of the owners.

Several instances have been published in which tubercle has been inoculated by the saliva. Of those cases of inoculation that one of us has met with are the following. A child with lupus of the face admitted that her mother had sometimes cleaned the face with a handkerchief moistened with saliva, and in reply to a question as to whether her mother had a cough the child at once replied that the doctors said that her mother had consumption. A subsequent inquiry amongst out-patients showed that this indelicate attention was very frequent, many of the mothers admitting that they had used this method on occasions Is this method of cleaning a child's face in an emergency entirely confined to the destitute?

Another case is that of a patient who has had phthisis for four years Some two or three years ago she suffered from a rash over her arms. The rash consisted of tiny red spots "not like nettlerash," although accompanied by intense itching, especially at night. She says that she scratched them and applied saliva to alleviate the irritation. There are a few slight scars marking the places where suppuration followed and on one of the scars is a ring of lupus nodules. (See Fig. 1.)

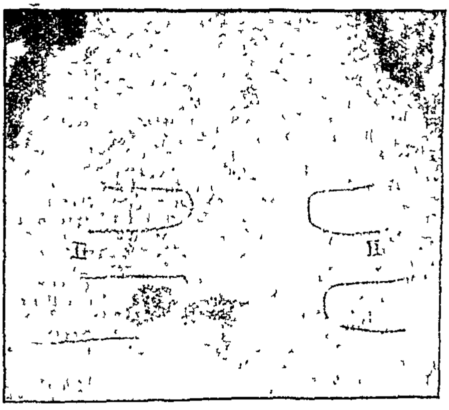
FIG. 1.



Lupus, inoculated by saliva, upon a scar, just above origin of the supinator longus Right arm.

Another case of auto-inoculation is that of a patient who has had phthisis for some six months. In August, 1908, she had a pimple over the right margin of the sternum opposite to the second intercostal space. Causing great irritation, the pimple was scratched and it broke. The patient frankly admits that she applied saliva to the small wound. The pimple healed and entirely disappeared. A few weeks afterwards, in the same place, a small flat lump appeared under the skin. The skin over the lump became thin and red, and later a discharge broke through the centre of the area *The disease has spread for one and a half inches* along the intercostal space and at the present time (December, 1908) there is an irregular line formed of thin red scar

FIG. 2.



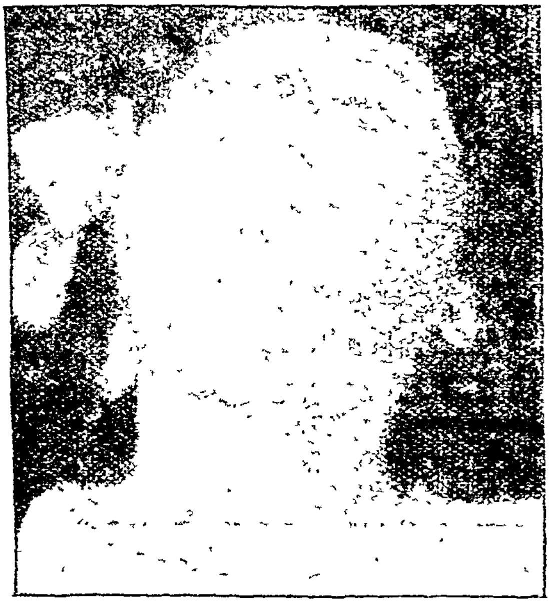
Lupus inoculated by saliva spreading along second intercostal space.

tissue with one or two yellowish scabs upon it. Beneath the unchanged skin at the outer end of the line two small flat lumps can be felt. (Fig. 2.)

The difference in the form of skin tuberculosis in the above two cases of auto-inoculation may be due to difference in depth of the inoculation, or possibly to a difference in the variety of tubercle bacillus.

In another case of a patient, aged 13 years, the position of the lupus is at least open to the suspicion of having been caused by the use of saliva. The mother is healthy, but seven of the mother's brothers and sisters have died from consumption. The child herself has signs of phthisis at one apex. A linear scar two inches long runs across the neck at the level of the edge of the dress. A streak of lupus was removed from here three years ago and there is now a recurrence at one end of the scar. There is no other patch of lupus on the face or neck. No history can be obtained of the garments having rubbed the neck, but the habit of softening with saliva any rough and scratchy material which chafes the neck is too common to be dismissed as an unlikely cause. It is difficult to remember such simple actions, especially in a disease where cause and effect are separated by such a long latent period. (Fig. 3.)

FIG 3.



A streak of lupus possibly due to inoculation by saliva.

Saliva is sometimes applied to the eyelids to allay irritation, but where a handkerchief is so commonly used for dabbing the part, a sputum-contaminated handkerchief entirely apart from the use of saliva must be at least as common a cause of lupus. Lupus of the nasal mucous membrane is probably always due to the use of a sputum-infected handkerchief and not to saliva. In this connexion it is interesting to observe how a child usually makes inspiratory rather than expiratory efforts when the nose is being wiped and must thereby assist in the infection of the mucous membrane.

Saliva is often used as a styptic, and those cases which Dr. R. B. Wild[1] recorded of lupus of the lobe of the ear following perforation were probably cases of inoculation by means of saliva, as we know that saliva is often used as a styptic in these cases when the wound is fresh and later to smooth the introduction of the ear-ring.

It is a practice very common amongst nursing women to apply saliva to the nipples to encourage the infant to take the breast. This must be looked upon as a possible source of infection in cases of tuberculosis of the breast, but what must be the almost inevitable result to the child of the tuberculous mother who moistens the nipple with her saliva? One great advantage of the boat-shaped bottle in the artificial feeding of infants is that it does not necessitate the nurse or mother drawing up the milk into the teat before introducing the teat into the mouth of the infant. This transference of the saliva, however, is an accidental use, but the teat both of the long-tubed and of the boat-shaped bottle is often moistened intentionally to encourage the child to accept it. Again, mothers and nurses often apply saliva to the rubber comforter for the same purpose. 50 out-patients were asked the following "leading" questions: "Were all your children bottle-fed?" If the answer was in the negative, then, "Did you find any difficulty in getting them to take the breast?" And then, "I suppose you always wet the nipple first with a finger moistened at the mouth?" It is probable that had one said "I suppose that you never wet the nipple with your saliva?" the proportion of affirmative answers would have been much smaller. However that may be, of the 50 mothers 41 had fed at least one child for a time at the breast; of these only three did not admit having moistened the nipple. One of these could not remember, another who was consumptive had just admitted that she had lost three children from tuberculosis, and the third mother was certain that she had never moistened the nipple. Amongst those who had so moistened the nipple two had lost several children from tuberculosis, the mothers being themselves tuberculous, one mother having lost all seven. Of the nine mothers who had never given the breast only one had not sucked or otherwise moistened the rubber teat. If the risk of infection bears any direct proportion to the amount of the saliva used, and as to this we can offer no data, then the breast-fed child would run a greater risk than the bottle-fed child where the mother was tuberculous. Some of these mothers mentioned, as a reason for not having given the breast to all their children, that they had suffered from "broken bosoms." To those who make a routine examination of the mouth in the out-patient department of a hospital such broken bosoms need little further explanation. In the case of the tuberculous mothers we readily grant that infection may be carried to the child in many other ways, but it would be difficult to find a more certain method, or one more easily obviated.

We do not state that the saliva is to be blamed as the means of contamination in a very large number of cases of pulmonary or other forms of tuberculosis. Such a statement might lead to a foolish scare on the one hand, or from such exaggeration, lead, on the other hand, to the neglect of easy and reasonable precautions. We sometimes overhear an argument used to encourage the nervous or discourage the particular, that we must all swallow or inhale many tubercle bacilli every day. Without accepting or disputing such a statement, we may fairly point out that the fact that you cannot make your boots absolutely clean should not prevent you from using the doormat. Do we not insist upon our consumptive patients expectorating their sputum, although we know that they must still continue to swallow large numbers of tubercle bacilli?

We would urge that all cases of pulmonary tuberculosis, at any rate, should be forbidden to close envelopes and stick stamps with their saliva and forbidden to moisten their fingers with saliva for any purpose whatsoever. There is little to be said in favour of such uses, and when we have admitted that they are convenient and very common, they remain disagreeable and dangerous. But since the non-tuberculous who moistens his fingers with saliva to turn the leaves of the office ledger or grip the handle of a spade immeasurably increases the risk to himself of the same habit in the tuberculous, and since the tuberculous patient has usually been included amongst the non-tuberculous for some months at any rate before his disease is discovered, some attempt should be made to reduce the frequency of this habit even if it is thought to be impossible to put an end to it. Surely it is not too much to ask that wherever there is an inkpot there should be a gum or finger damper, and that it should be taught in all schools that moistening the fingers with saliva is a dirty habit and a habit that is fraught with danger both to the possessor and to others.

Note.—Since writing the above one of us has met with two other cases of lupus of the face where there was a definite history of face cleaning with saliva by the pulmonary tuberculous, but in neither case was a history of previous breach of surface obtainable. No doubt in the skin department of a hospital many more cases would have been met with.

Clifton.

TWO UNUSUAL CONDITIONS OF THE GALL-BLADDER.

BY HUGH LETT, M.B., CH.B. VICT., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL.

CASE 1. *Axial rotation of the gall-bladder; strangulation.*—The patient, a woman, aged 72 years, was admitted to the London Hospital on August 1st, 1905, with the following history. Three days previously she had been suddenly seized with severe pain in the right hypochondrium which persisted until her admission to hospital. She had vomited four or five times and the bowels had not acted since the beginning of the attack. She had never had a similar attack before, had never been jaundiced, and so far as she knew had never passed any gall-stones. On admission her pulse was small and regular, and its rate was 100 per minute; her temperature was 101°F. She was not jaundiced. There was great tenderness and rigidity in the right hypochondrium, and a rounded tumour could be felt in the region of the gall-bladder; it was dull on percussion, and the dulness was continuous with the liver dulness. The lower abdomen was distended. A diagnosis of acute cholecystitis was made.

A vertical incision was made over the swelling. On opening the abdomen the tumour was seen to be an enlarged gall-bladder with numerous adhesions to the omentum and hepatic flexure of the colon. The gall-bladder itself was black, the size of a large pear, and there were a few patches of lymph on it and also on the upper surface of the liver. The adhesions were all sufficiently recent to admit of their being broken down by the finger; none were ligatured. The gall-bladder was tapped and a black fluid composed of altered blood and a little bile was drawn off. The wall of the gall-bladder was much thickened and stiff from hæmorrhage into it. On palpating the cystic duct a nodule was felt which I thought at first mi [illegible] nodule of carcinoma, but on [illegible] nd that it was due to axial [illegible] the cystic duct, the nodule h[illegible] ting of the duct. The twist was easily undone and consisted of four half turns from left to right. The gall-bladder, with part of the cystic duct, was rapidly excised and the stump of the duct was ligatured and covered by peritoneum. No gall-stones were found in the gall-bladder or in any of the bile-ducts. A tube containing a gauze drain was passed to the stump of the duct through a stab wound in the loin and the anterior incision was closed. The patient collapsed suddenly 12 hours after the operation and in spite of treatment died a few hours later.

Th[illegible] of [illegible] after its removal it was found to be completely covered by peritoneum and was attached to the liver only by a narrow mesentery which left the gall-bladder in the neighbourhood of the neck and the cystic duct. The specimen is now in the London Hospital Museum, No. 1395F.

[illegible] ie liver is variable. In t[illegible] a shallow fossa on the under surface of the right lobe of the liver and only the fundus and lower surface are covered by peritoneum. In other cases a bridge of liver tissue crosses it, or it may be almost completely surrounded by peritoneum and have a distinct mesentery. In 100 dissections of the gall-bladder and bile-ducts Brewer[1] found that in five cases the gall-bladder was only attached to the liver by means of a double fold of peritoneum which formed a distinct mesentery. Three of these, however, had a second mesentery which was attached to the duodenum and transverse colon and which was really an extension outwards of the lesser omentum. It is therefore exceptional to find a gall-bladder so surrounded by peritoneum that it is attached to the liver by a definite mesentery, but it is extremely rare to find one which is so completely surrounded by peritoneum that it is only attached to the liver by a narrow mesentery which leaves the gall-bladder in the region of its neck and does not extend on to its body at all. When this condition obtains, the gall-bladder swings free in the abdominal cavity attached only by a pedicle composed of this short mesentery with the cystic duct and vessels, so that axial rotation of the gall-bladder with torsion of the pedicle is not unlikely to occur.

Wendel[2] has reported a case of axial rotation of the gall-bladder also. The patient was a woman, aged 23 years, who first came under observation in November, 1895, for some gynæcological disorder. A moveable ovoid swelling was then discovered in the mesogastrium extending into the left lumbar region, but there were no symptoms which could be associated with it. In September, 1896, she had a severe attack of cholecystitis, and perforation of the gall-bladder probably took place. She refused to submit to operation, however, until the following March, when she could endure the pain and discomfort no longer. At the operation a large abscess was found, which communicated with the gall-bladder through a large perforation on its postero-external aspect. The gall-bladder contained many gall-stones, but a few had escaped and were lying loose in the abscess cavity. The cystic duct was extremely long; it measured three and a quarter inches from the anterior border of the liver to the neck of the gall-bladder and was twisted many times. The gall-bladder was completely surrounded by peritoneum, but the cystic duct had a mesentery about two inches long which was attached to the under surface of the liver. The length and extreme twisting of the duct are well shown in the illustration given in Wendel's article. This illustration is also represented in Bland-Sutton's "Gall-stones and Diseases of the Bile-ducts."

While this case described by Wendel resembles Case 1, it differs from it in many respects. In both cases the gall-bladder was entirely surrounded by peritoneum, and was attached to the liver by a narrow mesentery which, with the cystic duct and vessels, formed a pedicle, and in both cases there was rotation of the gall-bladder with torsion of the pedicle. In Wendel's case, however, the patient suffered from gall-stones, and acute cholecystitis with perforation of the gall-bladder occurred; the cystic duct, moreover, was extraordinarily long. He does not say whether there was any evidence of previous hæmorrhage into the wall of the gall-bladder, but only that, although the duct was twisted many times, gangrene had not supervened. It is remarkable that gangrene did not occur, for with such twisting of the duct the blood-supply through the cystic artery must have been cut off. Probably the nutrition of the gall-bladder was maintained by means of the adhesions between it and neighbouring structures, as is frequently the case in the somewhat analogous condition of torsion of the pedicle of an ovarian cyst. In Case 1 there were no gall-stones and the cystic duct was not unusually long, but torsion of the pedicle caused obstruction of the cystic vessels and strangulation of the gall-bladder.

CASE 2. *Primary carcinoma of the gall-bladder 21 months after cholecystotomy.*—The patient, a woman, aged 37 years, was admitted to the London Hospital, under the care of Mr. Jonathan Hutchinson, jun., on Nov. 19th, 1906. During the previous two years she had had four characteristic attacks of gall-stone colic accompanied by jaundice.

Laparotomy was performed by Mr. Hutchinson. The gall-bladder was opened and three large faceted gall-stones were removed; it also contained mucinous fluid and a large quantity of débris which had to be wiped from the mucous membrane of the gall-bladder. No stones were found in the hepatic or common ducts. The gall-bladder was drained and the patient made a good recovery. She remained quite well until May, 1908, when she began to have continuous pain in the right hypochondrium, with severe exacerbations every day. The pain was sharp and cutting in character and she described it as passing round the right side to the back. Recently it had been so bad that she could get no rest. There had been no jaundice since the operation.

The patient was readmitted to the hospital on August 6th, 1908. On examining the abdomen a rounded swelling was found in the right hypochondrium lying under the scar of the previous operation. It was smooth in outline, adherent to the anterior abdominal wall, and tender on palpation. There was no free fluid in the abdomen.

A vertical incision was made into the swelling and the diagnosis of malignant disease of the gall-bladder was confirmed. The wound was closed and two oval incisions were made, which were so placed that the gall-bladder and the overlying part of the abdominal wall to which it was adherent could be removed in one piece. There were numerous adhesions between the gall-bladder and the omentum; these were not broken down, but the gall-bladder was freed by dividing the omentum between ligatures. It was then found that the growth had passed beyond the gall-bladder and had invaded the adjacent part of the liver, and accordingly a wedge-shaped piece was excised from the right lobe, its base measuring about two and a half inches. The wound in the liver was closed by means of catgut sutures. The subsequent progress of the case was uneventful with the exception of an attack of bronchitis which slightly retarded convalescence. The wound healed by first intention.

---

[1] Annals of Surgery, vol. xxix., p. 721.

[2] Ibid., vol. xxvii., p. 199.

The specimen was composed of the gall-bladder and the adherent omentum, the overlying part of the liver, and part of the cystic duct. The walls of the gall-bladder were very much thickened and were obviously the seat of malignant disease which extended into the cystic duct. The growth projected into the cavity of the gall-bladder and partly filled it. There were no gall-stones in the gall-bladder or bile-ducts. Microscopically the growth was a columnar-celled-carcinoma.

Two similar cases have been reported. Lawford Knaggs[3] operated upon a woman, aged 69 years, in September, 1902. The gall-bladder was distended to the size of a fist and contained foul-smelling fluid with some pus. A single stone was felt in the cystic duct. This was squeezed back into the gall-bladder and was removed. The gall-bladder was very long and supple and not noticeably thickened; it was drained. The fistula persisted until the end of 1903, when it closed. Shortly afterwards the patient came under observation again on account of pain in the gall-bladder region which she thought was due to the closing of the fistula. Some thickening was felt under the scar of the old operation. On Jan. 23rd, 1904, a small incision was made over the closed sinus into the gall-bladder and some mucus and a little pus escaped. The mucous membrane was sutured to the skin. The patient ultimately died on Feb. 18th. At the post-mortem examination the walls of the gall-bladder were seen to be infiltrated with growth to the thickness of nearly half an inch, the growth extending to and involving the cystic duct. The growth involving the cystic duct had pressed upon and partially obstructed the commencement of the common duct. Above this stricture the ducts were markedly dilated and were the seat of suppurative cholangitis. No gall-stones were found. Microscopical examination of the growth showed it to be a columnar carcinoma.

Mayo Robson[4] performed cholecystotomy upon a woman, aged 57 years, in February, 1902. A stone was found in the cystic duct and was removed. In October, 1903, the gall-bladder and adjacent part of the liver were successfully excised. The gall-bladder was of the size of a small hen's egg and full of solid material. On incising it the swelling was found to be new growth which was infiltrating the adjacent parts of the liver.

The close connexion between carcinoma of the gall-bladder and gall-stones is now generally recognised, and Siegert[5] says that in 95 per cent. of cases of carcinoma of the gall-bladder and adjacent portions of the liver the malignant change is due to the chronic *irritation of gall-stones*. The frequency with which carcinoma of the gall-bladder has developed in connexion with gall-stones is often brought forward as one of the reasons for excising the gall-bladder in all cases when operating for gall-stones. On the other hand, when gall-stones by their irritation have given rise to carcinoma of the gall-bladder they are practically always found in the malignant gall-bladder, and it is extremely rare for carcinoma to follow cholecystotomy.

In April, 1905, G. R. Slade[6] published a paper containing some remarkable facts in connexion with gall-stones and malignant disease which he had observed while working in the Pathological Institute at the London Hospital. He particularly drew attention to the importance of chronic thickening of the wall of the gall-bladder, and pointed out that it should be viewed with the gravest suspicion and not lightly regarded as being due to chronic inflammation. In 12 cases the wall of the gall-bladder presented an appearance which at the time of the necropsy was described as chronic inflammatory thickening. In five of these cases carcinoma was found on microscopical examination. The remaining seven unfortunately were not examined microscopically, but to the naked eye they presented an appearance exactly similar to that of the five cases which were proved to be carcinomatous. He added that since he began in all such cases to examine the wall of the gall-bladder as a routine, he had in no instance failed to find carcinoma.

A few weeks after the appearance of Slade's paper H. A. T. Fairbank[7] briefly reported a case which had been operated upon by Mr. Stanley Boyd. Two gall-stones were impacted in the neck of the gall-bladder, which was kinked. Cholecystectomy was performed as it was thought to be the most satisfactory way of dealing with the case. The wall of the gall-bladder was thickened to a uniform degree. On microscopical examination it proved to be carcinomatous.

In an excellent chapter on cholecystectomy, Moynihan,[8] in pointing out that one of the arguments for cholecystectomy as opposed to cholecystotomy is based on the fact that gall-stones are responsible for so many cases of primary malignant disease of the gall-bladder, says that it must be shown that carcinoma of the gall-bladder has occurred after cholecystotomy, and this the cases reported by Lawford Knaggs, Mayo Robson, and myself certainly appear to do. It is remarkable that each of these three cases should have come under notice at about the same interval after the primary operation—viz., 15, 20, and 21 months respectively, and it raises the question whether early carcinomatous changes could have been already present in the gall-bladder at the primary operation. If so, the general rule that carcinoma of the gall-bladder does not occur after cholecystotomy holds good; but even if the gall-bladder were free from carcinoma at the time of the primary operation these three cases are in such an extremely small ratio to the cases which have not developed carcinoma after cholecystotomy that they cannot be regarded otherwise than as exceptions to the general rule. They cannot alter the generally accepted indications for cholecystectomy, but only serve to accentuate the importance of carefully examining the gall-bladder in every operation for gall-stones, and of regarding *cholecystectomy as an operation of necessity and not of choice* if there is any thickening or ulceration of its wall, or if its appearance or consistency is in any way suspicious.

I am much indebted to Mr. C. W. Mansell Moullin and Mr. Jonathan Hutchinson, jun., for whom I was acting when these two cases were admitted to hospital, for permission to record them.

A CASE OF VASCULAR DEGENERATION: A STUDY IN CARDIAC ARRHYTHMIA.

BY A. M. GOSSAGE, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, WESTMINSTER HOSPITAL.

THE patient, a German, aged 66 years, from whom the accompanying tracings were obtained, went to the Westminster Hospital complaining of general weakness, of dyspnœa on exertion, and of pain in the chest. On examination he was found to be a feeble man of spare habit, whose radial arteries were decidedly atheromatous, while the pulse was very irregular. It was noticed that there were frequent "intermissions" and that at times the rate of the pulse was infrequent and at other times of normal frequency, the less frequent rate being exactly half the more frequent. The chest was emphysematous and the heart was somewhat overlapped by lung. The apex beat was about half an inch outside the normal position. On auscultation the first sound was shorter than normal but there was no added sound. Not infrequently an extra-systole could be heard—i.e., a premature feeble systolic sound followed by a long pause. Beside these there were numerous pauses or intermissions during which no feeble sound was heard. During auscultation the halved rhythm did not happen to occur. The case was diagnosed as general vascular degeneration affecting the coronaries as well as other arteries. It was considered that owing to insufficient blood-supply to the cardiac walls

there was fibrosis of the heart and loss of contractile power in its muscle. The pain in the chest, which was partly constant, partly paroxysmal in character, brought on by exertion, was regarded as being of the nature of angina pectoris. This view was confirmed by the relief afforded by nitroglycerine.

Numerous tracings were taken from the patient, and these were interesting from the complicated nature of the irregularity of the rhythm and the difficulty in arriving at a correct interpretation of its causes. It was found necessary to take the tracings when the patient was sitting up in a chair, as the irregularity completely disappeared when he was lying down. No tracing could be obtained from the jugular vein except in the horizontal position and then not a satisfactory one; this, however, showed that the auricles were beating in their normal relation to the ventricles and that the interval between the auricular beat and the ventricular was of the normal length. Owing to the emphysematous condition of the lungs it was very difficult to get a tracing from the apex, and a cardiogram was only obtained after the patient had been under observation for several weeks. Thus at first the only tracings showing the irregularity were those obtained from the radial artery alone. From these it was possible to draw certain conclusions, but there were many doubtful points which were only cleared up by the cardiogram.

To begin with, the tracings showed a fair number of extra-systoles. In some of these the compensatory pause was complete, in others it was incomplete, which means that some of the extra-systoles were of the ventricular type, others of the auricular. The majority had, however, a complete compensatory pause, and so were of ventricular origin. An example is shown in Fig. 1, where the premature systole *x* is followed by a pause of such length that the sum of the intervals before and after it was equal to the period (8·5 fifths of a second) occupied by two normal beats. On looking at Fig. 1 another irregularity may be noticed. The beats are alternately large and small, but the pause before each small beat is longer by one-tenth of a second than that after it. The small beat here cannot be an extra-systole, since extra-systoles are always premature, whereas here the small beat is delayed. This is, then, a true alternating action of the heart, the beats occurring at regular intervals, but being alternately larger and smaller. The delay in the occurrence of the small beat in the radial is due to the fact that a feeble contraction takes longer to open the aortic valves than a strong one and takes longer to travel to the periphery; at the heart the beats occur at equal intervals of time. In animal experiments an alternating action of the heart has been shown to be due to loss of the contractile power of the muscle, and Hofmann and Wenckebach give the following explanation of its occurrence:—"Each beat of the heart destroys the contractility of the muscle and after the beat this contractility is gradually restored, but reaches its full extent before the arrival of the next beat. Slight variations in the length of the diastole make no difference in the size of the subsequent beat. Where contractility is depressed it takes longer to recover and has not fully recovered before the commencement of the next systole. Under these circumstances any increase in length of the diastole will be followed by a larger beat owing to the better recovery of the contractility; any decrease of diastole will be followed by a smaller beat. A large beat encroaches on the subsequent period of rest since it is not only larger in size but lasts longer. Hence after a large beat there is a shorter period of rest which, with depressed contractility, will cause the next beat to be small: the period of rest after this would be longer and so the next beat larger and the next pause shorter. Thus there would be alternately large and small beats occurring at regular intervals once this abnormal rhythm is started."

It is not surprising that an alternating action is specially prone to start with the large beat that occurs after the long compensatory pause after an extra-systole, as is the case in Fig. 1. An alternating action of the heart is thus a valuable sign of depressed contractility in human beings and its presence in this case confirms the view that the contractile power of the cardiac muscle is deficient.

In other tracings from the patient, as in Fig. 2, a small delayed beat is found after every second normal beat instead of there being an alternating action. Theoretically, it is difficult to account for this small beat as being due to depressed contractility unless there were some outside influence—e.g., nervous—which rhythmically lessened the contractility. Vagus influences are known to depress contractility, and Mackenzie[1] has recorded cases where small beats from depressed contractility occur quite irregularly. There is, however, another difficulty with regard to this interpretation of Fig. 2; the delay before the small beat is exceptionally long, longer than would be expected from the comparative slowness of its transmission to the wrist. In Fig. 2 are also shown some pauses, double the length of the normal pulse period, which might possibly be due to the small beat being too small to reach the wrist or to the small beat being entirely left out. In other tracings (see Fig. 3) there is a halved rhythm which one might explain as an alternating action where the small beat was either left out or too small to reach the wrist. Such a halved rhythm can be obtained with depressed contractility in animal experiments, being preceded by an alternating action in which the small beat gradually gets less and less. In human beings cases have been recorded of isolated intermissions of the pulse apparently due to loss of contractile power in the cardiac muscle, but so far no case of a halved rhythm due to this cause has been described, although its possibility has been acknowledged. Against this interpretation it might be urged that to produce a halved rhythm the contractility would have to be very gravely depressed, and yet my patient was capable of walking about. In two places marked *x* in the tracing Fig. 3 it will be noticed that a delayed small beat occurs and that in the first of these there appears to be another small beat before the delayed one. This is, however, not certain. The numbers below the tracing indicate the pulse periods in fifths of a second.

Fig. 4, in which a tracing from the apex was at last obtained, clears up all obscurities. Here several examples of delayed small beats appear and in each case the cardiogram shows that the small beat is preceded by another smaller beat, which is not large enough to produce a wave at the wrist. These beats, marked *x* in the apical tracing, are evidently interpolated extra-systoles. Interpolated extra-systoles are rare, but Mackenzie has shown that they do occur, particularly in senile hearts. The reason for the delay in the beat after these interpolated extra-systoles is that the conductivity has not fully recovered in the auriculo-ventricular bundle, so that the stimulus takes longer to pass across it, while the small size of this next beat is due to the contractility not having fully recovered. In the early part of Fig. 4 are two apparent intermissions. The apex tracing shows that here also an extra-systole is present, but this is later in its occurrence than the interpolated extra-systoles. Still the extra-systole is too small to give a wave at the wrist. Owing to the comparative lateness of this extra-systole the next stimulus from the great veins and auricles finds the properties of the ventricular muscle insufficiently recovered for a response to take place and a beat is left out, there being a full compensatory pause as usually occurs in ventricular extra-systoles. These points can be perhaps better appreciated from the diagrammatic representation of Fig. 4 given in Fig. 4a, where *As* represents the auricular systole, *A-V* the auriculo-ventricular interval, and *Vs* the ventricular systole. Here the marked lengthening of auriculo-ventricular interval after the interpolated extra-systoles is well shown. This tracing favours Mackenzie's view that extra-systoles start from the primitive cardiac tissue (i.e., the auriculo-ventricular bundle and its continuations) and that the cause of the compensatory pause after a ventricular extra-systole in man is that in these cases the conductivity of the bundle is depressed and has not sufficiently recovered to let the next stimulus through. It is just possible, however, in this case that the compensatory pause may be due to the contractility of the ventricles not having sufficiently recovered after the extra-systole. The explanation of the halved rhythm in this patient is evidently that it is in reality a bigeminal action of the heart, the second of the coupled beats not being large enough to reach the wrist. This is shown in the diagrammatic representation of Fig. 3 given in Fig. 3a.

This patient was evidently suffering from fibrosis of the heart, probably associated with atheroma of the coronaries. In consequence of this the contractile force of the muscle was deficient, leading to the pulsus alternans and to the attacks of angina pectoris. The fibrosis had probably invaded the *a.-v.* bundle, causing an increased irritability and hence numerous extra-systoles arising in the primitive tissue of which the bundle is composed. An important point to observe is the difficulty of the interpretation of the radial tracing alone, whereas when a simultaneous tracing was obtained from the apex to compare with the radial, the causation of the irregularity became quite clear.

SOME APPLICATIONS OF THE PRECIPITIN REACTION IN THE DIAGNOSIS OF HYDATID DISEASE.[1]

By D. A. WELSH, M.A., B.Sc., M.D. Edin.;
H. G. CHAPMAN, M.D., B.S. Melb.;
AND
J. Q. STOREY.

(*From the Physiological and Pathological Laboratories of the University of Sydney.*)

Results previously obtained.—In January, 1908, two of us[2] published an account of our experience with the precipitin reaction in hydatid disease, and quoted nine consecutive and unselected cases of hydatid invasion in all of which a well-marked precipitin reaction was obtained. In eight of these cases blood from the hydatid patient was collected in sterile glass pipettes on the morning of the day of operation; the hydatid fluid or cysts were obtained in sterile flasks in the afternoon; the patient's serum and the hydatid fluid were allowed to stand overnight in a cool chamber; and the test was made next morning about 24 hours after the blood had been collected. Control sera from healthy persons were taken at the same time as the sera to be tested and were kept in the same manner. From six to 12 drops of serum were shaken up with one cubic centimetre of clear hydatid fluid, precautions to minimise bacterial infection being taken, and the tubes were allowed to stand for 24 hours at room temperature before the precipitates were read. In these circumstances, with one exception, the patient's serum never failed to give a positive reaction with the hydatid fluid removed from his tissues. The single exception, however, yielded a precipitate when the patient's serum was tested with the hydatid fluid obtained from another patient. While this was our usual procedure, we also tested the serum of some of the patients, collected before operation, with hydatid fluids taken from other patients, and we obtained positive precipitin reactions in cases in which subsequent operation revealed undoubted hydatid invasion, and negative precipitin reactions in doubtful cases in which at operation hydatid cysts were not found. Notwithstanding our small series of cases, the fact that in every case the presence of the reaction corresponded with the presence of hydatid cysts, and the absence of the reaction with the absence of cysts, led us to the conclusion that in the precipitin reaction we had a valuable aid to the diagnosis of hydatid disease. We must, however, emphasise the fact that this striking evidence of the correlation of a specific [illegible] as obtained in the [illegible], since usually the [illegible] from the same patient and tested within 24 hours, or, when the serum and the hydatid fluid were obtained from different patients, the hydatid fluid had not often been kept for more than a few days.

Object of the present paper.—It was obvious, however, that if the test was to be of general value as a means of diagnosis we must have a method of storing for considerable periods of time hydatid fluid in such a form that it would be capable of giving a well-marked reaction with the sera of patients suffering from hydatid disease, and that it would not yield any reaction with sera obtained in other conditions of disease. Our present communication, which is of the nature of a progress report, deals mainly with the interactions of hydatid fluids (*a*) not derived from the patient whose serum was being tested, (*b*) of longer standing than those used in our first series of cases, and (*c*) subjected to various methods of treatment in order to preserve them in a sterile condition for many months. The conditions of experiment were, therefore, less favourable than in our first series of cases, and we may at once state that in this second series the amount of the precipitum in positive cases was on the whole smaller than in our first series, and that some cases of hydated invasion failed to give a satisfactory reaction with the hydatid fluids employed by us. Nevertheless, in no single instance did we obtain a positive reaction where hydatid invasion was afterwards proved *not to exist*, and *we were able to give a positive* diagnosis in some cases in which the clinical evidence was on the whole opposed to the probability of hydatid disease, our diagnosis being confirmed by subsequent operation.

Data on which paper is based.—Exclusive of control observations, this paper is based on 50 precipitin reactions tested in regard to 36 patients known or suspected to harbour hydatid cysts. Of these patients 20 were definitely proved to be infested by hydatids and 30 precipitin tests were carried out in regard to them in addition to the usual controls. The analysis of these 30 reactions, the nature of the hydatid fluids employed, and the results obtained constitute the substance of our paper. We may note, however, that of the other precipitin tests 11 were conducted with the serum of ten patients from whom hydatids were in all probability absent, since an operation, or the subsequent history, revealed the presence of some other condition (new growth, suppuration, calculus, &c.) sufficient to account for the symptoms. In all of these cases the precipitin reactions were negative. The remaining nine precipitin tests were made with the serum of six patients in whom an operation, or the progress of the case, was inconclusive as regards the presence or absence of hydatid invasion. Of these doubtful cases two gave a slight positive reaction and four a negative reaction. Since the diagnosis was doubtful we have not dealt further with this group of cases.

List of 20 Cases Investigated in which Conclusive Evidence of Hydatid Invasion was Obtained at Operation or Otherwise.

Case 1.—Male, 23 years; large single cyst of liver with clear contents.
Case 2.—Female, 40 years; multiple suppurating cysts of liver.
Case 3.—Female, 24 years; hydatid of liver.
Case 4.—Male, 39 years; multiple cysts in muscles of back; cysts densely matted and packed with minute secondary cysts.
Case 5.—Female, 12 years; multiple cysts of kidney.
Case 6.—Female, 26 years; large single cyst of liver with clear contents.
Case 7.—Male, 26 years; multiple cysts in kidney of at least ten years' duration.
[illegible]
Case 11.—Male, 51 years; cyst behind liver.
Case 12.—Male, 11 years; suppurating hydatid in left iliac region.
Case 13.—Male, 42 years, large cyst of liver with clear contents.
Case 14.—Female, 50 years, large, shrunken, degenerated cyst of liver with caseous, bile-stained contents.
Case 15.—Female, 28 years, medium cyst of liver with clear fluid contents
Case 16.—Male, 42 years; hydatid of liver.
Case 17.—Male, 35 years, hydatid of lung (?); no operation was performed, but patient coughed up a piece of hydatid membrane.
Case 18.—Female, 12 years; cyst of liver with clear fluid contents.
Case 19.—Female, 49 years; multiple cysts of liver, spleen, and peritoneum.
Case 20.—Male, 22 years; large cyst of liver with clear contents.

Analysis of the precipitin reactions obtained with various hydatid fluids tested with the sera of the patients in whom the presence of hydatid cysts was conclusively proved.—The tests may be arranged in the following groups according to the nature of the hydatid fluid employed in the interactions.

Group I.—In this group of seven tests we repeated the methods adopted in our previous investigation of allowing the serum of the patient to interact with the fresh untreated hydatid fluid taken from the cysts harboured by himself, or with similar fluid collected from another patient. In every instance but one definite evidence of a precipitate was obtained in 24 or 48 hours at room temperature. In two cases the precipitate was very slight, but distinct in comparison with the control tubes; in two cases the precipitate was well marked; and in two it was massive. In one case of long-standing hydatid invasion, Case 7, the reaction was indeterminate.

1. One cubic centimetre of fresh hydatid fluid from Case 4 interacting with nine drops of serum from the same case taken just before operation gave a well-marked precipitate.

---

[1] [illegible] sian Medical Congress, Melbourne,
[2] [illegible] asian Medical Gazette, 1908, and [illegible]

2. One cubic centimetre of fresh hydatid fluid from Case 6 interacting [illegible] drops of serum from the same patient before operation gave a [illegible]

[illegible] hydatid fluid from Case 6 passed through [illegible] ting with 16 drops of serum from the same [illegible] ielded a very large precipitate of four [illegible]

[illegible] hydatid fluid from Case 7 interacting with 12 drops of serum from the same case collected before operation gave an indeterminate reaction.

5. One cubic centimetre of fresh hydatid fluid from Case 7 interacting with 12 drops of serum taken before operation from Case 8 gave a well-marked reaction.

6. One cubic centimetre of hydatid fluid from Case 18, collected sterile and kept on ice, interacting with 11 *drops of serum, taken from* the same case five days after operation, gave a large precipitate exceeding two millimetres in depth.

7. One cubic centimetre of hydatid fluid *from* Case 18 kept sterile on ice for five days interacted with 11 drops of serum from Case 19 before operation and gave a slight positive reaction.

Group II.—The tests in this group were conducted with the fluid obtained from a large hydatid cyst of the liver in Case 1. The clear fluid was passed *through* a Chamberland filter, became accidentally infected, and was filtered again, thereafter remaining sterile. After the second filtration, and six days after removal from the patient, quantities of the fluid amounting to three cubic centimetres and four cubic centimetres were put into sterile tubes without further addiment, the tubes were plugged and allowed to stand at room temperature. It was then noticed that a deposit began slowly to separate out from the hydatid fluid. For a few days no deposit was seen at the foot of the tubes; by the end of a week a slight trace of deposit was visible; by the end of a month well-marked deposits were present, the fluid remaining quite sterile. With this fluid we tested the serum from each of two hydatid patients (other than the patients from whom the fluid had been obtained), but in each case the result was indeterminate, since the deposit was too scanty to warrant a positive diagnosis being made. Owing to its failure to elicit definite precipitates from the sera of two hydatid patients this fluid was discarded.

1. One cubic centimetre of hydatid fluid from Case 1 as above, six days after removal, interacted with 12 *drops of serum from* Case 2, collected one month after operation while small cysts continued to drain away from the wound. A large quantity of serum was obtained and four similar reactions were investigated, the tubes being allowed to stand at room temperature for 24 hours, at 37° C. for one hour, at 45° C. for one hour, and at 60° C. *for one hour*, but in every case the result was indeterminate.

2. Two cubic centimetres of hydatid fluid from Case 1 as above interacted with eight drops of *serum from Case* 3 *before operation*, but again the result was indeterminate

Group III.—A saline extract of hydatid membrane was used in the third group of tests. The membrane was dried in a desiccator over calcium chloride and at a temperature of 37° C. Six grammes of dried *membrane* were *ground up* in a mortar and extracted for 48 hours with 300 cubic centimetres of a 0·75 per cent. sodium chloride solution. The extract was then passed through a Chamberland filter. With the filtered extract was tested the serum from each of four hydatid patients, but in each case with negative results. It must be added, however, that in *one* instance, Case 5, the serum was not tested until three weeks after operation and only four drops were obtained; in another instance, Case 6, the serum before operation gave only a slight reaction with the fresh hydatid fluid from the same patient; in a third, Case 7, the reaction of the serum with the fresh fluid from the same patient was indeterminate; and in a fourth, Case 13, the serum was not otherwise tested.

1. One cubic centimetre of e[illegible] with four drops of serum from C[illegible] *tion while cysts were still being* [illegible]

2. One cubic centimetre of [illegible] serum from Case 6 before operation to give a negative reaction.

3. One cubic centimetre of extract interacted with 12 drops of serum taken before operation from Case 7 with a negative result.

4. One cubic centimetre of extract interacting with nine drops of serum from Case 13 gave a negative reaction.

Group IV.—The tests in this group were carried out with the hydatid fluid obtained from a liver cyst in Case 6. The clear fluid was passed through a Chamberland filter and thereafter remained sterile. It was stored in small flasks, and, after the lapse of a month, it was noticed that an abundant flocculent deposit had separated out in all the flasks, *the* superfluid remaining clear and sterile. This fluid had been tested with serum from the same patient one week after operation and gave a very large precipitate (cf. Group I., No. 3). It was then used for purposes of diagnosis to test the serum taken before operation *from seven different hydatid* patients, and gave distinct positive reactions with four of these and indeterminate reactions with the remaining three, in one of which the only cyst found was shrunken and degenerated. In two of the positive cases the circumstances were of more than usual interest. In Case 9 two separate precipitin tests were made in each instance with definitely positive results. Nevertheless, operation was delayed because the clinical signs pointed so strongly to *cirrhosis* of the liver. Later, however, an operation was performed and a hydatid cyst was found on the under surface of the liver compressing the portal vein. Again, in Case 11 a positive reaction was obtained, but at the first operation no lesion was found and the wound was closed up. A second precipitin test gave again a positive reaction, and a second operation was performed when a hydatid cyst behind the liver was found.

1. One cubic centimetre of fluid *from* Case 6, *one week* old, interacting with 12 drops of serum from Case 7 before operation gave a slight positive reaction. The serum from this case (7) gave a negative reaction with *extract of hydatid membrane (cf. Group III.*, No. 3) and an indeterminate reaction with the hydatid fluid from the same patient (cf. Group I., No. 4).

2. One cubic centimetre of hydatid fluid from Case 6, one month old, interacting with 10 drops of serum taken before *operation from* Case 9 gave a decided positive reaction. Operation was delayed (*vide supra*) and the test was repeated with similar results.

3. One cubic centimetre of hydatid fluid from Case 6, two months old, interacted with 13 drops of serum *taken before operation from* Case 10, but only a very slight precipitate was obtained and the result was [illegible] A few days later the test was repeated, but the result [illegible]

[illegible] hydatid fluid from Case 6, two months old, [illegible] s of serum from Case 11 before operation [illegible] *ion. At the first* operation no lesion was found, and the test was repeated with again a slight positive reaction. A sec[illegible] ation revealed the presence of a hydatid cyst (*vide supra*).

5. [illegible] hydatid fluid from Case 6, two months old, interacted with [illegible] serum taken before operation from Case 12 to give a slight positive reaction.

6. One cubic centimetre of hydatid fluid from Case 6, four months old, interacted with 11 drops of serum taken before operation from Case 14, but the precipitate was too slight to justify a positive diagnosis. At the [illegible] cyst was found.

[illegible] *from* Case 6, *four months old*, [illegible] Case 15 *before operation* gave an indeterminate result.

Group V.—Our fifth group of precipitin tests includes those conducted with clear hydatid fluid obtained from the liver cyst in Case 15 passed through a Chamberland filter and treated with *sodium arsenite, 50 cubic centimetres of the* filtrate receiving 0·5 *gramme of* sodium arsenite. With this fluid three tests were made on hydatid patients before operation, in two instances with positive results and *in* one instance with a negative result.

[illegible] from Case 15 + sodium [illegible] *taken before operation* [illegible]

[illegible] from Case 15 + sodium [illegible] Case 17 *before operation* [illegible]

3. One cubic centimetre of [illegible] from Case 15 + sodium arsenite interacted with 14 drops of serum *from* Case 20 before operation, but no precipitate was seen.

Discussion of results.—While we have obtained further evidence of recognisable and specific interactions between fluids from hydatid cysts and sera from hydatid patients, we have not been able to find a method of applying this reaction so that it will hold good *in* all cases in conditions of diagnosis. This failure appears to be due to difficulties relating to the serum of hydatid patients and to difficulties relating to the hydatid fluids.

In regard to the serum (antiserum) we must emphasise the great differences that exist between the hydatid antiserum *arising in the* human subject in conditions of accidental infection and precipitin antisera prepared by artificial injection of animals. In preparing a rabbit, in order to obtain a precipitin antiserum that will interact with blood serum or with egg-white to yield a good precipitate, moderate doses of the protein (from 0·5 to 1·0 gramme of dried protein) are introduced at intervals of two or three days until from 6 to 10 of such doses have been given, and the antiserum is withdrawn 10 or 14 days after the last injection. The precipitable content of such an artificial antiserum will be diminished, or may even disappear, if the injections are inadequate, excessive, irregular, or prolonged, or if the interval between the last injection and the withdrawal of the antiserum is too short or too long. With these somewhat rigid conditions essential to the preparation of a good precipitin antiserum we must contrast the conditions of protein interchange when the human subject becomes invaded by hydatid cysts. In the first place absorption of material from the hydatid cyst extends usually over a long period of time—certainly for months, often for many years—before the patient comes under observation, and the capacity of the human organism for reaction to the hydatid products may thus become exhausted. Moreover, the absorption of hydatid products may often be inadequate, and more often still it is probably irregular both in amount and in time.' On these grounds alone it is only reasonable to expect that the precipitable content of hydatid antisera from the human subject should inevitably be small in the majority of cases, and it is not surprising that in some cases it should be inappreciable.

In regard to the hydatid fluid we must note (*a*) that not *all hydatid fluids are equally capable of interacting with* hydatid antisera to give a precipitate, and that some appear to fail altogether; (*b*) that when hydatid fluid, filtered or unfiltered, is allowed to stand in a sterile condition a deposit slowly separates out and may form a considerable layer, and that this spontaneous precipitation may be associated with deterioration of the capacity of the fluid for interaction with hydatid antisera; and (*c*) that the low saline content of hydatid fluids may interfere with the precipitin reaction, since precipitin interactions are very susceptible to variations in the saline content of the fluid in which the interaction takes place. There may, however, be some way of overcoming the apparent unsuitability of some hydatid fluids for reaction with hydatid sera, for example, by modification of their saline content, but this last point did not occur to us while carrying out these tests.

Conclusions.—1. A precipitate was not obtained in any interaction between hydatid fluid and human serum from a patient not invaded by hydatid cysts. 2. Having regard to the long duration and probable irregularity of the interchange of protein molecules between a hydatid cyst and its human host, and having regard also to the possible unsuitability of the hydatid fluid, we must expect a certain number of precipitin tests to fail to give a satisfactory precipitate, and this has been our experience. 3. In the conditions of a diagnostic precipitin test as above described for patients suspected to harbour hydatid cysts, a negative reaction is inconclusive, but a positive reaction is conclusive of hydatid invasion, and the latter may be obtained in circumstances of clinical importance.

Sydney.

RECURRENT HÆMATOPORPHYRINURIA WITH TOXIC SYMPTOMS NOT DUE TO SULPHONAL.

BY W. LANGDON BROWN, M.A., M.D. CANTAB., F.R.C.P.,
PHYSICIAN TO THE METROPOLITAN HOSPITAL; MEDICAL REGISTRAR AND DEMONSTRATOR OF PHYSIOLOGY, ST. BARTHOLOMEW'S HOSPITAL;

AND

H. O. WILLIAMS, M.R.C.S. ENG., L.R.C.P. LOND.,
CASUALTY OFFICER AND REGISTRAR TO THE METROPOLITAN HOSPITAL.

HÆMATOPORPHYRIN is present in normal urine, though in such small quantities that it does not alter the colour or exhibit its typical bands on spectroscopic examination. The term "hæmatoporphyrinuria" is reserved for those cases in which enough of this pigment appears to render the urine either of a port-wine colour or of a dark-brown hue, when the spectroscope will at once reveal the cause of the alteration. Such hæmatoporphyrinuria occurs under two sets of conditions: (1) after sulphonal, trional, or tetronal have been administered, when it forms one of a group of toxic symptoms of grave import; and (2) a disturbance of pigment metabolism, continuous over long periods, or recurrent and paroxysmal, for which in some cases diffused morbid conditions of the liver appear to be mainly responsible.[1] In the majority of these instances it does not seem to have had any evil significance. Occasionally, however, cases of hæmatoporphyrinuria occur, which, though not due to any administered drug, present definite toxic symptoms resembling the sulphonal cases in important particulars. Of this the following appears to be an example.

In June, 1906, a married woman, aged 22 years, was admitted to the Metropolitan Hospital, under the care of Mr. W. D. Harmer, for a severe attack of abdominal pain with vomiting and constipation. The vomited material was deeply bile-stained but never fæcal. It was noted that the urine was claret-coloured and that it contained a few blood cells, though not nearly enough to account for the colour. A few granular and epithelial casts were present; there was no bile or pus. No spectroscopic examination of the urine was made. Mr. Harmer decided that the patient was not suffering from intestinal obstruction, so large enemata were given, the patient being placed on milk diet. There was no improvement in her condition until the sixth day after admission, when the vomiting stopped and the bowels became fairly regular. The urine was still claret-coloured when she was discharged. Soon after this she miscarried. The urine subsequently became normal in colour and she enjoyed her usual health until April, 1907, when she had another attack of abdominal pain, vomiting, and constipation, for which she was treated at an infirmary. During this attack the patient noticed that her urine again became dark. She was quite well within a week and the urine soon regained its natural colour. On Feb. 28th, 1908, she had her third attack of abdominal pain, vomiting, and constipation, for which she was admitted to the Metropolitan Hospital, under the care of Mr. Peter L. Daniel, who, deciding that there was no evidence of intestinal obstruction, transferred her to the medical wards, where she came under our observation. She was very thin, of a dark complexion, with a good deal of pigmentation on the face and abdomen. The tongue was coated with a thick brownish fur. The teeth were good. Nothing abnormal could be discovered in the chest and the reflexes were natural. The abdomen moved well; there was no rigidity, no tenderness on palpation, and no evidence of free fluid. The liver dulness was normal and the spleen was not palpable. The pain complained of was referred to the umbilicus. A small amount of blood was found to be oozing from the anus, but nothing abnormal could be felt on rectal or vaginal examination. The temperature was 98° F., the respirations were 30, and the pulse was 90. The blood pressure was 110 and the administration of two drachms of adrenalin chloride solution by the mouth did not raise it. The patient passed only small quantities of urine which was dark brown in colour and strongly acid. It contained no blood corpuscles, albumin, sugar, acetone, or diacetic acid. On spectroscopic examination two bands were seen, identical in position with those of oxyhæmoglobin, which were unaltered in position on the addition of reducing agents or glacial acetic acid. Dr. A. E. Garrod reminded one of us in conversation that hæmatoporphyrin was often in combination with metals when present in the urine, in which condition it shows these two bands instead of those of acid or alkaline hæmatoporphyrin. The urine was accordingly treated with strong hydrochloric acid, when it became purple in colour and now showed the two bands typical of acid hæmatoporphyrin, their centres being approximately λ 605 and λ 565. Both before and after treatment with acid the band of urobilin just beyond the F line in the blue was very distinct. A specimen of the urine was sent to Dr. Garrod, who very kindly confirmed the presence of hæmatoporphyrin and urobilin in it. The patient was still vomiting and had become very drowsy and delirious. She had three epileptiform fits lasting for about five minutes each. The temperature was slightly raised. Small doses of calomel were given, but the bowels only acted in response to enemata for the first five days. The combination of toxic symptoms with hæmatoporphyrinuria naturally led to the suspicion of sulphonal poisoning, so large doses of alkali in the form of sodium bicarbonate were given, as advocated by Franz Müller[2] and by Stockvis. On account of the scanty urine an [illegible] tincture of [illegible] blood [illegible] by Mr. [illegible] owed 5,920,000 red corpuscles, 100 per cent. of hæmoglobin, and *9000 leucocytes.* The differential count showed a curious alteration in the proportions, 36 per cent. being polymorphonuclear, 50 per cent. small lymphocytes, 12 per cent. large mononuclear, 3 per cent. eosinophiles, and 1 per cent. basophiles. On the next day she was much better and quite clear mentally, though much prostrated. Recovery was rapid, but the urine continued to be brown, though not so dark in colour, and it still showed well-marked bands of hæmatoporphyrin. Constipation was the chief trouble and enemata had to be resorted to frequently. The patient left the hospital apparently quite well on March 26th. She continued to take a mild laxative and periodically presented herself for examination. Week by week the urine became lighter in colour, though the bands could still be detected until the beginning of June, when they entirely disappeared after the administration of a drachm of magnesium sulphate three times a day for one week.

[1] Garrod · Transactions of the Pathological Society of London, 1894, vol lv., p. 142.

[2] Wiener Klinische Wochenschrift, 1894, S 252.

It will be noticed that the symptoms here described closely accord with those seen in the hæmatoporphyrinuria of sulphonal poisoning in which, Garrod and Hopkins[3] state, "vomiting, constipation (sometimes following an initial diarrhœa), and abdominal pain are the most constant symptoms. In a few cases febrile disturbance has been observed, but as a rule there is no rise of temperature." The patient denied, however, that she ever took any drugs except those given her by her medical attendant, who kindly informed us that he had never ordered her any sulphonal or trional. That these drugs were not responsible for her symptoms is further supported by the fact that she remained in hospital for a month, during which time no such drugs were given, and yet the hæmatoporphyrinuria persisted. It should be added that while in the surgical ward she was given a drachm of paraldehyde and eight grains of veronal, but the dark colour of the urine was noted before this, and we are not aware that these drugs have ever been found to produce hæmatoporphyrinuria.

Garrod has reviewed those cases of hæmatoporphyrinuria not due to sulphonal which had been recorded up to 1904. In that series there are only two which presented toxic symptoms similar to those here described. Ranking and Pardington[4] described this symptom in two women, aged 41 and 47 years respectively. The patients were both highly neurotic and subject to chronic gastric catarrh and menstrual disturbances. They were seized with vomiting, thirst, suprapubic pain, and profound prostration, but there were no signs of organic disease. They were in bed in different rooms of the same house, but were not related. One recovered, the other died. No sulphonal was given, and Ranking was convinced that in the fatal case, at any rate, none had been taken. A dose of acetanilide had been followed by some unpleasant symptoms which passed off, and in the second case acetanilide had not been given. We have found two other instances recorded since the publication of Garrod's paper.

Lestock Thornton[5] records the case of a man, aged 45 years, who was seized with griping pains in the abdomen, nausea, and slight diarrhœa. Then he passed some blood-stained mucus and some bright blood per rectum. There was tenderness over the ascending and transverse colon, but nothing could be felt on rectal examination. The urine was port-wine coloured but showed no blood to the guaiacum test. No grave symptoms were present at any time and the patient made a good recovery. Thornton considered that the symptoms could be most easily explained by a hæmorrhage high up in the colon. The difficulties in the way of this view will be discussed presently.

T. K. Munro[6] has reported three cases of hæmatoporphyrinuria not due to sulphonal, one of which appears to belong to the category now under consideration. A boy, aged seven years, had been subject to cyclical vomiting with acetonuria for two years. In the attack described he was very ill and could retain nothing. The vomit was coloured like coffee and he passed blood by the bowel. This attack lasted much longer than the former ones, though there were periods of several days in which vomiting did not occur. After it had lasted for about six weeks the urine for the first time was red in colour and was found to contain hæmatoporphyrin. This abnormal pigmentation of the urine continued until the boy died about a week later. By this time he was greatly emaciated. He had been free from vomiting for about six days before the end, but towards the close he threw up some blood on one or two occasions. At no time were drugs of the nature of sulphonal or trional administered.

The bleeding per rectum which occurred in Thornton's case, in Munro's case, and in our case, is of interest in view of Stockvis's suggestion that hæmatoporphyrinuria due to sulphonal is the result of hæmorrhage into the intestinal canal or its walls. Calvert[7] has recorded a case of hæmatoporphyrinuria in a woman, aged 32 years, after copious hæmatemesis from gastric ulcer, in which the patient made a good recovery. This might be held to support Stockvis's contention, though the patient stated that she had passed similar urine about a year previously when suffering from dyspepsia, but had no hæmatemesis or melæna. Patients often fail to notice the occurrence of melæna, however, and a stronger argument against Stockvis's view is provided by the fact that such hæmorrhages have usually been absent in sulphonal cases examined post mortem, while in other cases of hæmatemesis Garrod failed to find any noteworthy increase of urinary hæmatoporphyrin. The frequent association of hæmorrhage into some internal organ with hæmatoporphyrinuria, not due to sulphonal, is a noteworthy fact, whatever the explanation may be.

Recent additions to our knowledge of toxic alterations in the hæmoglobin molecule would suggest that the type of case here described is due to some intestinal intoxication. We advance this hypothesis with the more diffidence, since there is to-day a tendency to explain diseases, of which the pathology is unknown, in this way on inadequate grounds. The existence of intestinal intoxication is easy to assert, but difficult to prove.[8] The facts which seem to us to point to an intestinal intoxication are these: 1. The leading symptoms were those of an intense gastro-intestinal irritation, abdominal pain, vomiting, with the passage of blood per rectum, followed by much prostration, restlessness, and delirium. Similar symptoms were present in Ranking and Pardington's cases, in Munro's first case, and to a milder degree in Thornton's case also. The similarity of the symptoms with those of sulphonal poisoning suggest a toxic agent. 2. Hæmatoporphyrinuria has occurred in enteric fever (Soberheim[9]), and McCall Anderson[10] has met with it in recurrent hydroa æstivalis in two brothers. 3. The pronounced urobilin band shows that one body of putrefactive origin, at any rate, was being absorbed in excessive amount by the intestinal walls. 4. Sulphæmoglobinæmia occurs under conditions of constipation and is much relieved by systematic treatment with aperients. Van der Bergh, West and Wood Clarke,[11] Hurtley and Wood Clarke,[12] have shown that in the formation of sulphæmoglobin the blood pigment is first reduced and then combines with the sulphur. Now Laidlaw[13] found that hæmoglobin would break down into hæmatoporphyrin much more readily in the reduced state than when containing oxygen. This suggests that in both cases some reducing agent is at work, and the intestinal symptoms point to the alimentary canal as its source. Magnesium sulphate relieved West's case of sulphæmoglobinæmia and our case of hæmatoporphyrinuria. On this view we have in methæmoglobinæmia an interesting analogy with hæmatoporphyrinuria. The former has been proved to result either from drugs of the aniline class or from intestinal intoxication; the latter can be produced by sulphur-containing derivatives of the aldehydes and apparently by intestinal intoxication also.

In conclusion, it must be admitted that hæmatoporphyrin alone does not account altogether for the altered colour of the urine, as was pointed out by Hammersten. Garrod found that he could remove the hæmatoporphyrin so completely from the urine in one of his cases that its spectrum was no longer seen, without appreciably affecting the colour of the urine, while if he added this pigment to normal urine until its absorption bands were visible with as great intensity as in the darkest specimens, only a comparatively insignificant change of tint was produced. In the present case excess of alcohol precipitated a considerable quantity of the abnormal pigment. Alcohol acidified with acetic acid took up the hæmotoporphyrin from this, but left a brown pigment behind. The nature of this residue is at present unknown. Garrod and Hopkins think that in some instances much of it is a derivative of hæmatoporphyrin, but that even this cannot be asserted of all the cases. The large number of red corpuscles present in the case here described would seem to negative any excessive hæmolysis. This is in agreement with Garrod's conclusion that a perversion, rather than an increase of hæmoglobin katabolism is responsible.

NOTE ON A CASE OF INTUSSUSCEPTION OF THE SIGMOID FLEXURE OF THE COLON.

BY ALEXANDER DON, M.A., M.B., C.M. ABERD., F.R.C.S. EDIN.,
SURGEON TO, AND LECTURER ON CLINICAL SURGERY IN, THE ROYAL INFIRMARY, DUNDEE.

INTUSSUSCEPTION of the colon, simulating a simple prolapse of the rectum, is, judging from the small number of cases recorded in recent literature, a comparatively rare accident. In fact, intussusception in the adult is not often met with, and is usually caused by a polypus situated low down in the pelvic colon. The following case affords some points of interest that make it worth recording.

The patient, a female multipara, 44 years of age, was in her usual health up to August 31st, 1908, when, feeling out of sorts, she took a dose of Epsom salts and cream of tartar. Later, when at stool, she felt a "wrench" inside and something came out at her anus. A good deal of blood and mucus was passed. She was admitted to my ward on Sept. 1st, as a case of prolapse of the rectum, and was suffering a good deal from pain over the lower abdomen. A sausage-shaped tumour, from 8 to 10 inches in length, protruded from the anus. It was red and swollen and at the apex was a sloughing polypoid mass. The patent lumen was discharging mucus. She was vomiting a brownish fluid, not stercoraceous, and her pulse was good, its rate being 60 per minute. Two hours later she was given chloroform with the object of reducing the prolapse per anum. On examination the finger could be passed into the rectum between the tumour and the sphincter without obstruction from the cul-de-sac. The polypus had a fairly broad base and was sloughing at its posterior segment. A circular ligature was applied and the mass was cut away flush with the mucosa. An attempt was then made to reduce the bowel with one hand in the rectum and the other steadying the tumour extra-abdominally, but only about six inches of the intussusception could be thus returned. The apex was fixed and it was feared that further manipulation might cause rupture; and, as there was doubt both as to the nature of the polypus and the vitality of the mesenteric sector laparotomy was performed. The abdominal wall was unusually filthy, as the patient was suffering from what proved to be a pustular scabies all over the body, and especially marked by scratches and small ulcers over the lower abdomen. The skin was cleaned as usual with a depilatory containing oxide of lime and sulphide of soda, and the edge of the wound was sutured to sterile lint as soon as the median incision was made, thus shutting off the septic surroundings as far as possible. The tumour was easily located and brought out. It consisted of colon entirely, and its distance from the anus was about 20 inches. The intussusception was easily reduced, but its site, with about three inches of healthy bowel on either side, was fixed outside the abdominal wall. Dr. A. Leitch examined the polypus microscopically and reported it to be a simple villous papilloma.

An opening in the bowel was made next day without any anæsthetic. The mesenteric segment from which the tumour arose was necrotic, and the whole mass was removed, the lower opening being closed by circular ligature and the mesentery tied *en masse*. This caused considerable pain. The artificial anus acted well, and the patient quickly regained her normal strength. An attempt was made to get the skin cleaned prior to closing the colostomy, as, owing to the urgency of her condition on admission, little could be done then. The real nature of the skin rash was not suspected, and ordinary measures did not improve the condition to any extent, especially round the wound. The left hypogastric region was the least septic, as well as nearest the descending colon, and I decided to enter the abdomen there. Owing to the great length of the sigmoid and mesosigmoid, I anticipated little difficulty in doing a lateral anastomosis and excising the colostomy ends after evaginating them through the colostomy opening. As such an operation was likely to take some time, the patient was given a hypodermic injection of a quarter of a grain of morphia and 1-100th grain of scopolamine on the night before the operation, and a similar dose on the next morning. The operation lasted nearly two hours, yet less than one ounce of chloroform was used and the patient slept on for five hours after the operation. There was no shock, the pulse being quite slow, though occasionally missing a beat towards the end of the operation.

On opening the abdomen the two ends of bowel were sought for, when it was found that the lower end was fairly tense, being held up by a twist round the upper end. The upper end was pulled out, crushed by the enterotribe as near the colostomy opening as possible, ligatured, and both ends invaginated by purse-string sutures. These were reinforced by a continuous Lembert. The mesocolon of the colostomy end was next ligatured piecemeal, each part being divided between the ligature and the bowel immediately the ligature was tied. There was practically no hæmorrhage. The rectal end was then brought out and treated in a similar fashion. The two ends of the bowel were now laid side by side and a lateral anastomosis was made, leaving an opening of about 1½ inches. There was some difficulty in doing this outside the abdomen owing to the amount of sigmoid, about 12 inches, which had already been resected. The ligatures on the mesocolon were tied together in a mass and a few stitches added to close the rent in the mesocolon. An attempt was then made to evaginate the two loops of bowel connected with the colostomy opening from the inside through their central openings. This was the most difficult part of the operation and in both cases the finger was pushed through the side of the bowel where section of the mesocolon had left it uncovered by peritoneum, but as this happened after nearly complete evagination, and as there were no fæces in the parts, no harm resulted, though it is hardly possible that no organisms reached the peritoneum during the withdrawal of the finger. The lateral incision was closed by layer sutures of silk. The two ends of the bowel protruding through the mesial openings were ligatured with strong catgut and cut away flush. A sterile dressing was applied to both wounds.

On the next morning the temperature rose to 102° F. and the pulse-rate to 112. On the second day after the operation the central wound was smelling badly and the projecting bowel was black and necrosed. The temperature was then 100°. A sterile gauze dressing was reapplied after sprinkling the sloughs with iodoform. During the next few days the patient's condition was rather poor and she complained of pain in the left side, and on the ninth day after the operation the side wound was seen to be bulging and was opened, when a quantity of pus and a gauze swab escaped. Recovery after this, so far as the abdomen was concerned, was uneventful, but later the patient developed a high temperature due to a septic ulcer of the tonsil, with some arthritic effusion, from which she soon recovered. The tonsillar ulcer yielded to specific treatment.

Looking back over the case, the following reflections are suggested:—1. Would it not have been better to have simply anchored the doubtfully necrosed area at the first operation with gauze tampons till its vitality or otherwise could have been ascertained, or to have excised it at once? 2. Would not the ordinary method of closing the colostomy wound by excision of the opening and lateral anastomosis through the same opening, even with its septic surroundings, have been safer? A gauze drain could have been left in as a safeguard. 3. Would this method of evagination have been more satisfactory if the mesentery had been doubly tied before division and the bowel pulled out by a pair of long forceps instead of evaginated with the finger from the inside? This could have been done more easily if the external openings had first been stretched a little and the apex of the loop then seized by an assistant with forceps, the operator guiding the forceps internally.

Maunsell's method of dealing with intussusception did not seem well adapted to this case owing to the high origin of the trouble, and the union at the mesenteric border is always a weak spot. Bishop records a case where he first did a colostomy, but the advantage of such a preliminary step in preference to treating the whole condition through a cœliotomy wound is not very apparent.[1] Oderfeld's operation,[2] with immediate resection, is the best yet suggested when the conditions of the patient and of the bowel are satisfactory, but as in simple resection any paralysis of the bowels would tend to a rupture at the suture line, the intussusceptum should always be removed per anum at the time of the operation, and the lower bowel irrigated with warm sterile salt solution.

The usual method of closing a colostomy wound by excision is not very satisfactory, inasmuch as the surrounding skin cannot be rendered sterile and a general peritonitis cannot with certainty be avoided. With thin and lax abdominal walls the method here adopted is not difficult, and the colostomy wound could be excised after the pieces of bowel have been evaginated if preferred. This would open up the peritoneal cavity, but there would be no manipulation of its contents through the opening. The external ligature round the bowel approximates serous to serous coats, and could be done with more safety if the peritoneum were fixed to the skin at the first operation. A second closing might be necessary to prevent hernia, but the whole aim of the surgeon should be the safety of the patient and not the brilliancy of the operation.

Dundee.

A CASE OF DISEASE OF THE HIP-JOINT DUE TO STREPTOCOCCAL INVASION, WITH SECONDARY MANIFESTATIONS IN OTHER PARTS.

BY W. OLIVER BEDDARD, L.R.C.P. LOND., M.R.C.S. ENG.

THE following notes on a case of disease of the hip-joint, proved to be due to streptococcal invasion, may seem worth recording as showing the resemblance which it bore in early stages to tuberculous disease and the rapidity with which destruction of bone took place, practically without pain or more than slight disturbance of temperature, and also adduce some evidence as to the value of treatment by a vaccine prepared from the patient's bacteria.

The patient, aged 12 years, a healthy-looking, well-nourished boy, was first seen on Sept. 14th, 1907. He then complained of pain on the outer side of the right thigh. He could move about the room with the aid of a stick, holding the right leg flexed at the hip and knee so that the toes only touched the ground. Pain was felt in the thigh only; none in the hip or knee. On examination there was found to be no tenderness of muscle in the area of pain and no tenderness of the femur. The hip-joint was held fixed and any attempt to move the joint or to extend the knee caused the occurrence of pain in the thigh; no fulness or fluctuation in connexion with the hip could be detected; there was lordosis of the spine. Eight days previously the patient had complained of pain in the thigh which had caused him to be somewhat lame for three days, when it disappeared entirely, so that he could run about and play lawn-tennis. On Sept. 13th he had again become a little lame and was kept awake that night by pain in his thigh. There was no history of illness; he was in particularly good health, having recently returned from a holiday at the seaside. There was no definite history of injury beyond that ten days previously he had been on a water-shute. On the first trip he sat in front and when he got off he said his back hurt him; however, he made other trips, taking a back seat so as not to feel the bump so much; he also made some trips on a switch-back railway. He seemed quite well on arrival home and made no further reference to pain.

As a result of extension the limb became quite straight and pain subsided in a few days. Deep pressure over the hip-joint elicited some signs of pain. On Oct. 5th a skiagraph was taken by Dr. A. H. Greg. This revealed nothing abnormal in the hip-joint. From Sept. 14th to Nov. 26th (the ninth to eighty-second days of illness) the patient, treated with rest and extension, was practically free from symptoms except for occasional attacks of sickness lasting one or two days. There was at the latter date no real or apparent difference in the length of the legs. The temperature was only slightly above normal. On Nov. 26th (the eighty-second day of illness) a soft semi-fluctuating swelling appeared in the right groin; there was great tenderness over and around the swelling and over the great trochanter. The temperature at night was 103° F. This swelling rather quickly subsided and had disappeared by Dec. 3rd. On the 11th (the ninety-seventh day of illness) the patient complained of pain in the left side, particularly after coughing, and that he had been kept awake by throbbing pain. Examination revealed a tender swelling which gave a doughy sensation to the touch, its centre was a little to the inner side of the middle of Poupart's ligament, it encroached two or three inches over the abdomen, obliterating resonance, also over the upper part of Scarpa's triangle. There was no tenderness on the posterior aspect of the hip. The swelling appeared to be confined to the tissues over the joint, the joint itself not being involved. The boy looked ill and flushed. The morning temperature was 99°, that of the evening being 102°. This swelling gradually subsided, leaving the inguinal glands hard and tender. On the 16th (the one hundred and second day of illness) there was a similar tender swelling at the upper part of the inner side of the thigh on the same side, which gradually extended downwards along the inner side of the thigh from the apex of Scarpa's triangle to the popliteal space and eventually as far as the middle of the back of the calf. As the swelling passed down the leg it cleared up above. After all swelling had disappeared hard tender glands could be felt in the popliteal space and in the back of the calf. Whilst this train of symptoms was in progress the temperature was fairly consistently in the morning 100° and in the evening 101°; at its conclusion it fell practically to normal. On Jan. 4th, 1908 (the one hundred and twenty-first day of illness), a blood examination was made by Dr. E. E. Klein with cultures on surface agar plate, surface agar tube, and broth tube. The result showed the blood to be quite sterile, no microbe of any sort having developed in these cultures after 48 hours at 37° C. In the meanwhile the right hip treated with rest and extension had given rise to little trouble. There was some enlargement of the great trochanter, which was a little tender on pressure; there was also some tenderness over the posterior aspect of the joint. On Feb. 6th (the one hundred and fifty-fourth day of illness) the patient complained of painful twitchings in the right thigh, the pain being chiefly felt on the outer side of the thigh (the original site of pain); there was also some pain in the knee. On examination there was found to be a more general enlargement of the trochanter, which was also more tender; pressure upon it elicited spasms in the muscles of the thigh. These starting pains were not severe; they occurred only during the daytime at intervals of two or three hours and ceased entirely after a few days. On the 16th (the one hundred and sixty-fourth day of illness) there were obvious differences in the bony relations of the two hips and the right leg showed nearly one inch of shortening. Dr. Greg took another skiagraph, concerning which he made the following report:—

> The femur is displaced upwards, the upper lip of the acetabulum is absent. The whole surface of the acetabulum is rough. The femur is intact but very much rarefied, not, however, with the rarefaction typical of caries. The dislocation is accompanied by extreme external rotation. The points unlike ordinary tuberculous disease are the dislocation without any destruction of head of femur (this I have not seen in tubercle) and the rarefaction not being typical. The destruction of the acetabulum has been very rapid. The x ray examination strongly supports the view that the disease is not tuberculous.

On Feb. 23rd (the one hundred and seventieth day of illness) an operation for excision of the hip was performed by Mr. E. M. Corner, the anæsthetic being administered by Dr. Z. Mennell. An anterior incision was made over the joint, upon opening which a little clear fluid escaped. The head of the femur having been cleared with an elevator and the neck sawn through the head of the bone was extracted. The bone removed was exceedingly light and friable; portions of it were immediately placed in a sterilised bottle for examination by Dr. Klein. Exploration of the acetabulum showed it to be extensively destroyed. A false acetabulum had been formed above the real one. The old acetabulum was removed entire—it consisted merely of a shell of friable bone; the new one was also easily removed almost entire; above and [illegible] around these aceta[illegible] Only remnants of [illegible] was encountered [illegible] thoroughly curette[illegible] The wound was co[illegible] healed by first in[illegible]

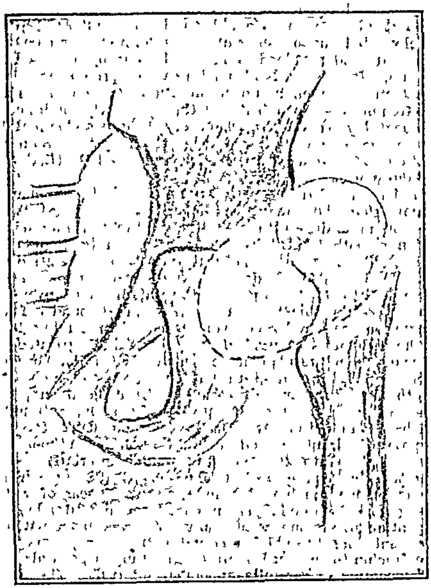
[2] Centralblatt fur Chirurgie, No. 10, 1899.



Outline drawing of the deformity. (From a skiagram.)

On March 6th (the one hundred and eighty-third day of illness) the patient's right knee was found to be swollen. Examination showed the knee to be tender to touch; downward pressure upon the patella so as to bring its posterior surface in contact with the condyle of the femur caused much pain; there was no pain except when the knee was touched. There was a considerable amount of fluid in the joint. The synovial membrane appeared distinctly thickened [illegible] but rather tended to increase. The knee gave a doughy sensation to the touch. Dr. Klein reported as follows:—

[illegible] the microscope exhibited distinct streptococci: some of these were short, composed of four cocci; others were longer, up to [illegible] colonies, which in two days caused distinct liquefaction. When liquefaction has well progressed—i.e., after about a week—the liquefied [illegible]

From the Louis Jenner Clinical Laboratory, to which Mr. Corner sent portions of bone, the reply, as the result of an examination of the microscopic sections, was that they presented "no evidence of tuberculosis." [illegible] ness, though [illegible] dily losing [illegible] in a very wa[illegible], the appetite was very poor, and any attempt to increase the amount of food resulted in troublesome sickness. A curious symptom which persisted through the illness was desquamation of the skin; this occurred constantly all over the body but was most marked on [illegible] case that the sheet upo[illegible] with epithelial scales. [illegible] such an extent as to leave raw tender places on the toes. Associated with this desquamative process was a marked tendency to the formation of sores. These sores would result from the pressure of the softly-padded leather used in connexion with the extension apparatus. The sores were shallow with shelving sides, healing slowly under thick scab; they proved a difficulty in carrying out treatment by extension. The first injection of vaccine was given on March 1st; they were continued for eight injections at intervals of four days. The progress of the case from this time onward was entirely satisfactory. The boy's condition wonderfully improved, he rapidly regained the loss of flesh, the sickness ceased, the sores healed, and the desquamation disappeared.

At the present time (one year after operation) the patient is able to walk with the aid of a walking stick; there is shortening of the right leg to the extent of about one inch; the right knee is somewhat enlarged, its range of movement has steadily increased so that it can now be almost completely flexed.

On reviewing the case one cannot but feel a regret that the nature of the micro-organism was not discovered earlier and a vaccine prepared therefrom used, but there were obvious difficulties in the absence of signs of fluid or pus in the hip-joint and the negative evidence of the early x rays and blood examination. Bearing in mind the threatening aspect of the knee-joint and its almost certain identity with the disease in the hip, it seems reasonable to believe that the course of this destructive disease might have been cut short by the early use of a vaccine. The difficulty which presents itself is, how could a portion of the bacterial tissue have been obtained in the early stage of the disease without exposing the patient to grave risk, when there appeared to be no symptom which indicated the unlikelihood of recovery under expectant treatment?

It would seem possible, had the blood examination been made during the time of the acute manifestations in the left leg, pointing to systemic invasion, or a culture have been made from lymph, withdrawn by a syringe, from swelling, that the microbe might have been then found.

It is instructive to notice that the x rays proved of no practical value in the early stages, as was also the case in another patient, shown at the Hospital for Sick Children, Great Ormond-street,[1] who presented an almost precisely similar clinical picture, but later they demonstrated the condition very clearly and accurately. The resemblance which such a case bears to tuberculous disease makes the diagnosis a matter of great importance and of considerable difficulty. As to the mode of infection in this particular case there is no evidence; there were no symptoms of even trivial illness preceding its onset.

Twickenham.

AMERICAN PROCTOLOGIC SOCIETY.—The eleventh annual meeting of this society will take place at Atlantic City, New Jersey, on June 7th and 8th. An interesting programme has been set down for discussion. The President of the Congress is Dr. George B. Evans of Dayton, Ohio, and the secretary is Dr. Lewis H. Adler, jun., of Philadelphia.

AN INTERESTING CASE OF APPENDICITIS: PERFORATION; OPERATION; RECOVERY.

BY T. WILSON PARRY, M.A., M.D., B.C. CANTAB.

THIS case of appendicitis is interesting because the patient was only 16 months old, while the condition was otherwise unusual. Moreover, the patient when an infant five months old suffered from fistula in ano, and it is not often that a medical man is called upon to attend a patient for two rare surgical affections in the first six months of life.

The patient was a boy, who was born on June 10th, 1907. He was a posthumous child, his father dying at the age of 33 years, after a short three days' illness, three weeks before the child was born, of what was called an acute asthmatical attack. I did not attend him, but am informed that he had had a bad attack of influenza in the preceding December, from which he never properly picked up, losing flesh steadily, till this acute attack intervened, from which he did not recover. There appears to have been a history of tuberculosis. When the child was a month old the mother noticed when bathing him a thickening of about the size of a small pea situated deeply in the right ischio-rectal fossa. The child had no pain and I left instructions that it should be carefully watched by the mother and if it grew larger or altered in any way I was to be immediately informed. When the child was four months old the little place had slowly become larger, so that I was able to detect fluctuation. On Oct. 7th I cut down under an anæsthetic, evacuated a few drops of pus, thoroughly scraped the part, and expected it to heal up forthwith. It did not heal and a second "pointing" occurred, not far from the original one, but not communicating with it, which I also opened. There were now two separate sinuses for a few days till the last one that was opened suddenly closed up. Although I could not discover any opening into the rectum I naturally began to consider it to be a case of fistula in ano. Mr. G. B. Mower White, who kindly met me in consultation, confirmed my diagnosis and told me that it was the first case of fistula in ano he had seen in an infant. I passed a probe in the usual manner through the wound into the rectum, cut down upon it, scraped thoroughly and dressed in the accustomed way for fistula, and the case healed soundly in one month's time.

That fistula in ano is an exceedingly rare affection in children under two years of age there can be no question. I have been unable to find a case recorded. I have been unable to discover whether the fistula in this instance was, or was not, of tuberculous origin.

I was called again to attend the same little patient on Oct. 9th, 1908. The mother told me he had had a restless night, whimpering and tossing incessantly. His fingers had been constantly in his mouth and he appeared to be cutting one of his four remaining still uncut molars. Two months previously to this he had had a teething attack accompanied by an obstinate paresis of the bowel which had lasted five weeks, and which aperients and enemata had the greatest difficulty in overcoming. Since that time, however, the child had been in excellent health. His mother told me that his bowels had been properly opened on the preceding day, but she had given him a dose of castor oil that morning before I came. On examination the temperature was slightly subnormal, there was no sickness, and the abdomen (usually large) was neither distended nor at all rigid. In the evening the temperature rose to 102° F., but there was still no sickness or abdominal rigidity. As the bowels had not been opened I gave an enema of plain warm water and the result was good. On the next morning (Oct. 10th) the temperature was again subnormal and I may here say, as it became a point of special interest in the case, that with one exception, and that when it rose only four points, the temperature remained subnormal during the whole of the rest of the attack both before and after operation. In the evening, as the bowels had not acted, I gave another enema, but this time only with slight success, what was passed being extremely offensive. There was still no sickness, but a slight abdominal rigidity had appeared which was more marked over the right abdomen. During the next two days (Oct. 11th and 12th) sickness intervened and there was undoubted pain in the abdomen, which, however, was much relieved by frequently applied hot fomentations. The pulse was good. In the evening of Oct. 12th when I called I found the child asleep and I was enabled to partly examine the right iliac fossa without waking the child up, only eliciting a single cry when my finger touched the bottom of the fossa. I could feel no lump and the abdominal rigidity appeared to be less, though there still existed a noticeable difference between that on the right and that on the left sides. I was now able to eliminate intussusception, no elongated tumour being discoverable, no tenesmus having occurred, and no blood or mucus having been passed per rectum. It was clearly also not a case of primary intestinal obstruction. Summing up the situation my feeling was that the trouble was appendical and this was partly confirmed on the next day (Oct. 13th), when very definite abdominal distension first made its appearance, which by the evening of that day became much increased, and I asked Dr. G. F. Still to kindly meet me in consultation.

Under chloroform we were both able to feel, on bimanual examination, abdominally and rectally, a thickening between the examining fingers a little to the right of the middle line, which we both decided was more than probably an inflamed and swollen appendix. Surgical aid became imperative and Mr. H. Stansfield Collier who had been summoned cut down a little to the right of the middle line, over the spot where the thickness had been felt, and found a fæcal concretion, rather larger than a cherry-stone, lying loose in the abdominal cavity. He then carefully separated the appendix from the bladder, to which viscus it had become adherent, and removed it. It measured two inches in length, was large and club-shaped at the distal end, and was perforated about half an inch from the extremity. Further, an incision was made in each flank for the purpose of drainage and a rubber drainage-tube was inserted also into the operation wound anteriorly. The operation was performed at 9.30 P.M., after which an enema of one drachm of brandy in two ounces of water was given. At midnight an enema of one drachm of turpentine in six ounces of soapy water was given without any result and the child was fed entirely on panopepton (one drachm to an ounce of water) given in teaspoonfuls and half-spoonfuls at carefully appointed intervals. The child was continuously restless all night, but kept down what food was taken till 12.40 P.M. on the next day (Oct. *14th*), when vomiting again returned. This occurred at three other times during the day. At 2 P.M. the tube in the operation wound was removed and a six-ounce enema of turpentine and soapy water was given per rectum when some flatus was passed. At 4 P.M. a quarter of a grain of calomel was given and at 9.30 P.M. another injection of turpentine and soapy water was administered, but with no result. On Oct. 15th the child vomited eight times. At 9 A.M. I gave three enemata consecutively, each consisting of a drachm of turpentine, a drachm of ether-soap, and six ounces of water, but there was still no action of the bowels. In spite of this last-mentioned fact abdominal distension was markedly less, so much so indeed that a drainage-tube in the right flank became bent at an angle, the skin moving downwards fully three-quarters of an inch. As the tube was now rendered useless by virtue of the kink produced I removed it. I now put the child on one-eighth of a grain of calomel every two hours to endeavour to create a peristalsis, and these powders were continued until a full grain of the salt was given. The result was excellent. After the second powder had been given the vomiting ceased, and when at 6 P.M. I again repeated my three consecutive enemata of the morning a fairly good motion with much flatus was passed. At 1.30 A.M. on the 16th the child was very restless and in much pain, but the passing of a rectal tube liberated a large quantity of flatus and gave immediate relief. An enema was again given at 4.30 A.M., but without success; but at 6 A.M. a small motion was passed naturally. At 4.30 P.M. another enema was given and this time a good result was obtained. I now took the child off panopepton and put him entirely on two drachms of Theinhardt's food with one and a half ounces of milk in six ounces of water. Flatus was now passed frequently. On the 17th the milk was increased by half an ounce in each feed of six ounces. The bowels acted twice slightly and once well. On the 18th I removed the third tube. The discharge from the wounds was now not nearly so offensive. The wounds were dressed twice a day and the discharge, when thick, scanty, and offensive, was thinned and increased by lightly packing the wounds with ribbon gauze soaked in a 2 per cent. solution of both citrate of soda and sodium chloride. From this time forward the child made an uninterrupted recovery. By the end of the third week the wound in the left flank was entirely healed, while those in the middle and in the right flank were reduced to small healthily healing sinuses. At the end of the month all the wounds were sealed.

True appendicitis is a rare disease in children under two years of age. Before the year 1897 no cases were recorded in the epitome of diseases to be found in the annual reports of the Hospital for Sick Children, Great Ormond-street. In that year there was a case in a child, aged 22 months, which passed off successfully without an operation. In 1902 there was a child, aged four months, with appendicitis in a hernial sac; an operation was performed and the child recovered. In 1903 a child, aged 21 months, suffering from some other disease, had a passing mild attack of appendicitis while in the wards of the hospital and got well without an operation. In 1905 there was a child, aged eight months, who had a ruptured appendix with general peritonitis; an operation took place, but the child died. In 1907 there were three cases of appendicitis, but all of them in hernial sacs, and these were all operated upon successfully. Summing up, then, since 1907 there were seven cases in all of appendicitis occurring in children under the age of two years. Of this number four of the cases were ones of appendicitis in hernial sacs. Of the remaining three cases, two of them appear to have been under physicians and did not pass into the hands of the surgeon, while the last one—the only one of this kind operated upon—died. This case of mine, therefore, in relationship to these statistics, stands alone, as it is the only case of a child under two years of age who, suffering with acute appendicitis not in a hernial sac, has been operated upon successfully and has lived. I happen to have heard privately of one other case similar to this one now published. The child was 14 months old and made an excellent recovery. Mr. Collier was the surgeon in this case also.

Crouch End Hill, N.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ECLAMPSIA.

BY W. BOXER MAYNE, M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT MEDICAL OFFICER, GREAT WESTERN RAILWAY WORKS, AND SURGEON TO THE VICTORIA HOSPITAL, SWINDON.

A FEW months ago I reported in these columns a case of eclampsia in which the convulsions at once ceased on the production and completion of labour, the morphia treatment having apparently failed. The following case, an example of the fact that some source of irritation to the system—viz., the pregnant uterus—is not by any means a necessary element in the causation of this terrible complication of labour, would, however, point to the great efficacy, in certain cases at least, of hypodermic injections of morphia in the control of the fits, even though the kidneys may be markedly deranged.

The patient, a young primipara, aged 21 years, had noticed that for about a month prior to her confinement her face in the morning had been somewhat puffed and she had been troubled with almost intolerable irritation of the skin. I was called to her confinement at about 9.30 o'clock one evening finding full dilatation and the pains weak. Progress being consequently slow I delivered with forceps. All went well till the placenta, &c., were passing the vulva when (at 10.15 P.M.) there came on a severe eclamptic fit and in the course of the next ten minutes two more occurred.

From this time to 7 A.M. on the next day the patient had no recurrence of the fits, and though at times she was restless and very sick she continued in a very heavy, dazed state. At 7 A.M. a sixth fit occurred, whereupon I gave the patient a hypodermic injection of a quarter of a grain of morphia and one-sixtieth of a grain of strychnine. At 9.30 and at 10.15 A.M. the seventh and eighth fits respectively occurred. I now, in addition to the hot packs that had been kept up throughout, gave the patient a saline injection of four pints (together with two drachms of bromide of potassium, 20 grains of chloral, one ounce of sulphate of magnesia, and one ounce c

bowel. Ur

absolutely motionless; at 1 o'clock, however, she had her ninth fit, half an hour later a tenth, followed shortly by the eleventh, each being as severe as the first. I then gave another hypodermic injection of half a grain of morphia. By 9.30 P.M. the patient had much improved and had become sufficiently sensible to be induced to drink two glasses of milk and some diaphoretic and bromide mixture. A very good night followed, the patient taking milk at intervals, and by the next morning she was able to recognise those tending her. During the day urine was passed freely, which on examination was found to contain much albumin. Whether on the second day of her illness the patient passed any urine it is hard to say since she was constantly in the hot wet pack. All albumin had disappeared by the fourth day.

Whilst taking precautions to produce abundant perspiration and free action of the bowels my experience in five at least out of six cases has been that hypodermic administration of morphia is a most valuable method of treatment in eclampsia whether occurring before or after labour. I only regret that in the case just described I did not push the morphia more.

Swindon.

A CASE OF VENTRICULAR HÆMORRHAGE SIMULATING ECLAMPSIA.

BY ALAN RANDLE, M.D., B.S. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE ASSISTANT MEDICAL OFFICER TO THE LAMBETH INFIRMARY.

I WAS called out early on Nov. 16th, 1908, to attend a multipara, aged 43 years, for a "fit." The friends gave a history of headache and lassitude for 10 days, culminating in a general convulsion lasting a few minutes. The patient was found to be six months pregnant but the fœtal heart was not audible. She was semi-conscious; the conjunctiva reflex was present and the pupils were equal and small; there was intermittent clonic twitching of the left shoulder muscles and purposive movements were retained; both knee-jerks were absent but no paralysis was discoverable. With the fit there had been no cry, no biting of the tongue, and no incontinence. The tongue was fairly clean and the pulse was weak and rapid. After staying with the patient for some time she recovered full consciousness and understood what was said to her, but could not speak. She was moved into the infirmary, where she recovered speech. The urine was found to be half solid with albumin, which only very gradually decreased under treatment. On the day after admission the patient got out of bed as she saw imaginary people in the ward; on the whole she was lethargic, but would speak when roused. She suffered intermittently from paralysis of the bladder and the bowel, necessitating catheter and enema; occasionally these functions were normal. Sensation was of the disordered type seen in hysteria, with no true anæsthesia. The patient was sometimes able to talk to her husband, though not to me. Five days after admission she gave birth to a six months partly macerated male fœtus, the skin peeling off it in places. The general condition slightly improved after labour, which was absolutely painless, and a confident diagnosis was made of eclampsia, with a large superadded functional element, accounting for her retention, disordered sensation, and intermittent aphasia. The patient continued in much the same state for three more days, when the pulse-rate went up to 130. On the next evening she had a fit after an enema. There was a general tonic spasm, followed by restless movements; the left pupil was dilated and fixed, oval in shape, with the long axis vertical. The right pupil was normal and the conjunctival reflex was preserved on that side. She soon became fully conscious again and spoke to her husband. On the next morning she had two fits of the same nature and during the second she stopped breathing, although the heart continued regular and strong. Artificial respiration was carried out, but the heart gradually weakened and stopped.

At the post-mortem examination it was found that the kidneys were of the red granular type and that the liver was deeply congested, but there were no hæmorrhages into it or under the capsule. The heart was hypertrophied, but there was no atheroma of the vessels. There were a few minute hæmorrhages on the surface of the brain and a right ventricular hæmorrhage apparently starting from an anterior perforating artery and later bursting into the ventricle. Some of the hæmorrhage was old and the brain was softened and pigmented (even some of that apparently in the ventricle); the rest of the hæmorrhage was recent and it nearly filled both ventricles, extending down the iter to the fourth ventricle, pressure on the respiratory and vaso-motor centres obviously being the cause of death, the respiratory succumbing first.

Although cerebral hæmorrhage often complicates eclampsia this does not seem to me to be a case of the diseases co-existing. The liver and the kidneys were not typical of the condition, nor were the convulsions epileptiform in character. The pregnancy would undoubtedly much aggravate the existing renal disease and lead to a great rise in blood pressure, this in its turn leading to the hæmorrhage. The intermittent nature of the signs would seem to be due to the free absorption of lymph under pressure by the choroid plexus. I have reported the case owing to the great initial difficulty in diagnosis leading to serious error in prognosis.

I am much indebted to Dr. M. H. Quarry, the medical superintendent of the Lambeth Infirmary, for permission to publish this case.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Gas in the Stomach.—Port-wine Coloured Urine.

A MEETING of this section was held on March 26th, Dr. W. G. SMITH, the President, being in the chair.

Mr. F. K. CAHILL read a paper on Gas in the Stomach. He defined the terms "fermentation" and "putrefaction"—the former being mainly applicable to the decomposition of "carbohydrates," the latter to the decomposition of "proteids" and "fats." The end-products of each process were discussed. The causal factors in the production of gastric gas were considered under the following heads:—(1) Air swallowing; (2) chemical gastric respiration; (3) mechanical gastric respiration; (4) inorganic production of CO_2; (5) organic production of CO_2 and associated gases; and (6) spasm of cardia or pressure from without. The treatment of the various causes—including "lavage," diet, rectal feeding, and drugs—was referred to, and a plea was made for the more careful investigation of the causes of "flatulency."—The PRESIDENT took exception to the distinction drawn between fermentation and putrefaction. He looked on putrefaction as a mere accident of decomposition; it was simply fermentation *plus* smell. He was not hopeful of the possibilities of intestinal antiseptic treatment, as none of the things used had come up to expectation.—Dr. M. F. COX said that it was a rare thing for an amount of air capable of causing trouble to get into the stomach by swallowing. He thought the troubles must be looked for within. They had such cases where *mental* trouble or sudden shock had led to gas being formed by a process which was probably neither fermentation nor putrefaction, and in which a great amount of misery and depression was relieved by the expulsion of gas. In such cases he thought the subjective sensations were as much to be accounted for by the depression associated with mental causes as by poisoning of the blood by the by-products of digestion, or the uneliminated products of liver digestion.—Sir JOHN W. MOORE said that people with bad teeth who could not masticate their food swallowed with it very considerable quantities of air. They were familiar also with the connexion between cardiac and vascular lesions and gas in the stomach. It was exceedingly hard to disinfect either the stomach or intestines, but symptoms could often be relieved by attention to the toilet of the mouth.—Mr. CAHILL, in reply, said that the distinction drawn between "fermentation" and "putrefaction" was only for clinical use, seeing that the processes exhibited no absolute line of demarcation. The stress laid on air swallowing by Sir John Moore was in agreement with the observations of himself. An illustrative case of inflammable gas (CH_4) was quoted, a parallel to that noted by the President from the work of Sir Henry Marsh.

Dr. A. R. PARSONS read notes on a fatal case of Port-wine Coloured Urine (Hæmatoporphyrinuria). The patient came under his care early in June suffering from diffuse abdominal pain, vomiting, and constipation. The urine, on standing, become of a deep port-wine colour (specimen exhibited). It contained neither albumin nor blood. Neither trional nor sulphonal had been administered at this time. After ten days the patient improved and went away for a change. The symptoms, however, recurred and she was admitted to hospital towards the end of June. Abdominal pain was present Sleeplessness was pronounced, and she was given on four consecutive nights 15 grains of trional. The urine was of a similar colour to that passed early in her illness Towards the end of the first week after admittance she complained of severe pain in her feet, and on July 7th her arms were almost powerless and she was so ill and feeble that she could barely move in bed. On July 10th the rectal sphincter was relaxed and she commenced to pass fæces under her. A few days later swallowing became difficult and death took place in a little over two weeks after her admission to hospital and in less than seven weeks from the onset of her symptoms. Specimens of the urine passed shortly after her admission to hospital and a day or two before her death were exhibited. They were of a rich port-wine colour and, though nearly three years old, were acid in reaction and showed no evidence of decomposition. Though hæmatoporphyrin was probably present, the red colour was not due to this substance, and it was considered that the term hæmatoporphyrinuria applied to urine of this class was misleading.—The paper was discussed by the PRESIDENT and Dr. EUSTACE.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 2nd, Dr. W. H. Cheetham being in the chair.—Dr. T. Churton read a paper on Some Recent Compensation for Accident Cases. He said that in the examination of such cases six questions occur: (1) Does any lesion really exist, and, if so, where? (2) What is its nature? (3) Was it caused, either wholly or partly, by the alleged injury? (4) Was the injury accidental? (5) Will recovery take place? (6) and, if so, in how long? Upon (1) some suggestions were made concerning the investigation of symptoms. Upon (2) it was held that in a disputed case each of the medical witnesses should be required to state in writing the reasons for his opinion as to (*a*) the exact *site* of the lesion which is causing the symptoms; (*b*) its *nature*, considered as a distinct and separate problem; (*c*) its complete *causation*, with an estimate of the share taken therein by the injury, either directly or by its effects, acting in their turn as causes. If, for example, one man asserts that in some defined part of the nervous system there is a chronic inflammation—a pericellular or perineuronic lesion—of traumatic origin, and another maintains that there is no inflammation, but only (so-called) functional disorder, intracellular, and a metabolic hurrying or slowing, or a biochemical change—or, it may be, that there is no lesion of any kind, they should give their reasons in such a form that they could be submitted to a selected neurologist of judicial position and rank. And the same with respect to any other lesion, medical or surgical. Upon (3) a distinction was drawn between causes which were essential, determining, and contributory. And it was argued that if in a mass of interdependent organs like the body, a lesion produced by mechanical or other force gave rise to a succession [illegible] causes, the injury must be held [illegible] It appeared to have been maintained by at least one insurance office that the effects of an "accident" must be immediate, direct, unaided, almost instantaneous, and although they may not be instantly recognisable, must b[illegible] occurred at the time of the [illegible] and were not introduced after it. The insurer's view is that a true accident, however small, is the link in the chain of causation against which he wishes to insure. Other causes he may avoid or remove or o[illegible] by definition unavoidable. 4[illegible] be used sometimes to mean the *force applied*—as in the case of death from pneumonia occurring six days after a fall upon wet ground, in which the question before the Court of Appeal was whether death was due to the accident, meaning the shock produced by the (admittedly accidental) fall—and sometimes to mean the mode or the circumstances in which the force was applied, as in the cases of anthrax in a wool-sorter, heat-stroke in a fireman on a liner, and lead poisoning in a plumber, in which the question was whether the bacillus, the chemical, and the thermal force, acknowledged to be the cause of death in the respective cases, was an accident in the sense of having been acquired or *applied accidentally.* Dr. Churton doubted whether any condition or event which might be expected to occur in, and as a part of, the ordinary day's work, anything foreseen and certain to happen often or even occasionally, could properly be called an accident. Special terms and agreements should be made for hazardous employments.—Dr. Alexander D. Sharp read a paper on Modern Methods of Examining the Larynx, Trachea, Bronchi, and Œsophagus. Brüning's bronchoscope, together [illegible] of the larynx, trachea, and bronchi. It was pointed out that unnecessarily strong solutions of cocaine were generally recommended and that a perfect anæsthesia could be obtained by using a 5 per cent. spray for the pharynx, 10 per cent. application for the posterior surface of the epiglottis, and from 10 to 15 per cent. for the trachea and bronchi. Cases of temporary aphonia following bronchoscopy were attributed to faulty anæsthesia and indifferent manipulation. In order to get an extensive view within the trachea, the distal end of the bronchoscope must be controlled so as to keep it in the centre of, and parallel with, the trachea, as there was a tendency for the end of the tube to [illegible] be exercised [illegible] introduced to [illegible] against the [illegible].—Dr. E. F. Trevelyan showed a woman, aged 25 years, with Double Arm Paralysis of Plexus Type after Influenza. Recovery had already lar[illegible] was improv[illegible] Fractured [illegible] down of th[illegible] rapid consolidation occurred under antisyphilitic treatment. —Cases and specimens were also shown by Mr. J. Stewart, Mr. A. E. A. Pearson, Mr. B. G. A. Moynihan, Dr. A. Bronner, Mr. J. F. Dobson, Mr. W. O. Morton, Dr. A. G. Barrs, and Mr. E. Solly.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on March 10th, Colonel D. [illegible]l Army Medical College, [illegible]W. W. O. Beveridge, [illegible] Some Recent Methods of [illegible] the process of Letts and [illegible]olved oxygen in sewage [illegible]f apparatus for observing [illegible]n by polluted waters, [illegible]elf for extracting the total gases in sewage. Major Beveridge prefaced his demonstration by a few remarks on the importance of the fact that as an immediate and essential result of the mixing of a sewage effluent with a tidal water the more or less complete absorption of the oxygen dissolved in the latter takes place. It was, therefore, necessary in the case of any sewage to know its purity or the degree of putrescible matter present by ascertaining, on the one hand, the amount of dissolved oxygen present in the sewage, and, on the other, by estimating the amount of oxygen it was able to take up, which might be termed its "oxygen appetite." Taking a tidal water composed of equal parts of salt and fresh water, the lecturer pointed out that whereas saturation might be represented by a volume of 6·20 cubic centimetres of oxygen per litre, the lowest limit to which it was safe to de-oxygenate such a water was about 3·4 cubic centimetres per litre. Below this point there would be danger of destruction to fish. Proceeding Major Beveridge demonstrated the process of Letts and Blake for estimating the amount of oxygen dissolved in an effluent. This process depended on the fact that oxygen dissolved in water was absorbed by a ferrous salt plus an alkali (i.e., ferrous hydrate). The amount of oxygen dissolved in an effluent [illegible] adding a definite quantity of [illegible] excess of ammonia. The [illegible]he ferrous hydrate, and the amount of hydrate so attacked was calculated by the amount left unaffected. The latter was estimated by titration against a standard solution of an oxidising agent—e.g., bichromate of potassium. It was advised that the suspended matters should be removed and estimated separately, as small variations in these might affect the result. Major Beveridge then demonstrated Adeney's process for the estimation of the amount of oxygen absorbed by a sewage, and the rate of its absorption, in which the partial vacuum caused by the absorption of oxygen in one flask was measured by the rise of fluid produced in another flask connected by a glass tube. Finally a method was shown devised by Major Beveridge for the extraction of all the gases in a sewage by a process of boiling under reduced pressure, the gases so extracted being collected and afterwards analysed in a specially modified Orsat gas apparatus.—Mr. N. Bishop Harman demonstrated a piece of apparatus, giving a diaphragm test for binocular vision, founded on the fact that when a man with normal vision in both eyes looks through a hole in a diaphragm held at some little distance from him the eyes look crosswise through the opening, the left half of the field being viewed by the right eye, and the right half by the left eye. The instrument consists of a flat ruler 44 centimetres long with a rack at one end to hold the test-object cards and a screen at 11 centimetres from the rack in which an aperture, either round or square, of an area of 1·7 square centimetres is cut. The test objects are of different natures, written [illegible] patterns for children and un[illegible]es of the test are to determine [illegible]he vision in the two eyes, to [illegible]ce, or any defect of binocular vision, to exercise the vision in squinting eyes, to detect malingerers feigning monocular blindness, and to demonstrate certain physiological phenomena connected with the perception and suppression of images. The method of working was then demonstrated by Mr. Bishop Harman, and the meeting closed with a vote of thanks to him for his demonstration.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 2nd, Mr. Edward Sergeant, the President, being in the chair.—A discussion was opened by Dr. John Robertson upon the Prevention of Tuberculosis among Cattle. He pointed out in the first instance that stock-owners sustained a very considerable loss owing to the general wasting which occurred in cattle from the disease, from the inability to guarantee to the butcher freedom from tuberculous disease, and from the shortening of the milking period of good milkers by probably 50 per cent. The principal methods which had been proposed for clearing herds of tuberculosis were those of Professor Bang, Professor Ostertag, and of von Behring. The essentials of Bang's method were: (1) the testing of all animals with tuberculin; (2) the complete and continuous separation of the reactors from the non-reactors, with the necessary d[illegible] all calves on tubercle-free mil[illegible] all non-reacting animals; (5) [illegible] the most profitable time; and (6) the slaughter of all animals with udder tu[illegible] placed on con[illegible] investigation, [illegible] its success upo[illegible] to the tubercle bacillus by the injection of attenuated cultures. Dr. Robertson considered that Bang's method was the only reasonable one for general adoption. Every opportunity must be given for the establishment of an efficient public health veterinary staff for the examination of dairy cattle, and cowsheds must be brought up to a reasonable standard, for to attempt to reduce tuberculosis in insanitary cowsheds would be a mischievous waste of money. It had been ascertained in Birmingham as the result of the operation of the model milk clauses that 14 per cent. of the churns of milk coming into the town contained tuberculous milk so that some protective measures were necessary. A scheme on the lines of that suggested by Bang had been adopted and was being carried out in cowsheds situated within a radius of ten miles from Birmingham. A certificate was issued quarterly to those farmers who kept their herds free from tuberculosis and a list of such farmers was printed and supplied to any inhabitant of Birmingham who desired to have one.—Sir Shirley Murphy said that it was clearly to the interest of the dairyman to eliminate from his herd tuberculous cattle. He asked whether cowsheds were really necessary and thought that if cows were left to live in the open as nature intended they might predict that tuberculosis would be very much lessened. He insisted upon the necessity for branding every cow found to be tuberculous; otherwise an animal which had been tested and found to react could be disposed of and traced only with the greatest difficulty.—Dr. J. Niven regarded as an essential part of the programme the alteration of existing cowsheds, but it was not easy to see how that could be brought about, for the sanitary authorities were so largely composed of those interested. All milk dealers he thought should be required to provide themselves with a certificate stating that their cowsheds were good. He doubted if farmers could be prevailed upon to keep their cattle in the open, for more food would be required.—Dr. Chalmers urged that farmers should protect themselves against loss by insurance.—Dr. F. E. Fremantle, speaking from the point of view of the producer, feared that the interests of the town and country were divergent, and pointed out that if the cost of production were increased and the price of milk raised the result would probably be an increased consumption of condensed milk among the poorer classes. He was not sanguine of poor people demanding a pure milk-supply at an enhanced cost.—The President deplored the fact that in many country districts there was practically no inspection of cowsheds at all. He cited one district in which modified regulations were adopted, but the chairman of the sanitary authority frankly asserted that they were of such a character that they need not be carried out.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 1st, Mr. R. F. Jowers, the President, being in the chair.—Sir Malcolm Morris gave an address upon Eczema, its Nature and Treatment. He said that he would consider first the eczema of the young child, then that of puberty, then that of adult life, and if time allowed that of old age. The following is an abstract of his remarks: If a child six months old is brought with weeping eczema of the face and scalp use hot boric fomentations to get off the crusts; do not allow soap and water. Then powder with emol keleet, which is genuine fuller's earth, adding perhaps zinc oleate and boric acid, or calamine lotion. In acute eczema at all ages do not use ointments until the discharge stage is over. When the discharge has stopped use a zinc or zinc and ichthyol cream. Internally small doses of mercury are beneficial. Vaccination rarely "takes" during an acute eczema, and should be postponed until the eczema is entirely cured, or it may cause a fresh attack. Powdered oleate of zinc rubbed in is the best preventive of a relapse. If the child is seen early with only a little scurfiness of the face or a crust on the scalp, boric acid ointment or oil should be ordered, and very little washing allowed. If a child aged 14 years be brought with eczema (*a*) inquire if there have been attacks in infancy, if so, similar treatment is applicable; (*b*) examine the palms of the hands and soles of the feet for xeroderma, dry smooth palms, and keratosis pilaris of the extensor surfaces. In this case prolonged baths, the use of soap and glycerine, are indicated; the sweat glands do not act properly. (*c*) If there are patches on the arms or legs alternating with asthma or other nervous phenomena the eczema is of the neurotic type which goes on all through life. It is very pruriginous, very excitable. Tar should be used to allay irritation, arsenic internally, or a visit to the arsenical springs of La Bourboule or Levico may do great good. In adults if there are symmetrical scaly patches, examine the head for scurf, eczema seborrhœicum, but this must be distinguished from pityriasis rosea, which begins with a circular patch on the trunk or limbs, looking like ringworm; this is followed by a general eruption which does not spread below the knees or elbows. For seborrhœic eczema use soap and water followed by mild sulphur ointment, and for the scurfy scalp resorcin in vaselin. Weak red oxide of mercury ointment or one of carbolic and menthol or lotions of tar may also be useful. Sea-bathing and wetting the head every day make eczema worse. At the change of life the most prevalent trouble is acne rosacea, eczema of the face, arms, and vulva. For this aperients and tonics judiciously combined, as in the mist. ferri sulph. c. quin., are most valuable; ichthyol internally. Externally soothing remedies, such as calamine lotion, tinted ointments of boracic, ichthyol, or weak sulphur or resorcin.—The paper was discussed by the President, Dr. Walter Broadbent, and Dr. C. F. Bailey, and a hearty vote of thanks was passed to Sir Malcolm Morris.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on April 7th, Mr. W. Coates, the President, being in the chair.—Mr. J. E. Platt related a case in which he had excised a considerable portion of the Radial Artery in a case of Suppurative Arteritis leading to Secondary Hæmorrhage. The patient, a boy, aged four years, was admitted to the Royal Infirmary with a very extensive deep cellulitis of the forearm. Incisions were made on the day of admission, but two days later hæmorrhage occurred and the brachial artery was tied. Eight days afterwards hæmorrhage again occurred and it was therefore decided to open up the wounds and to search for the bleeding vessel. The upper part of the radial artery was found to be in a sloughy condition and two inches of the vessel were removed, the divided ends being ligatured with catgut. The patient, although greatly exhausted at the time of operation, afterwards recovered well and the functional use of the arm was perfect. Mr. Platt also referred to a similar case which he brought before the society 15 years previously in which he had removed four inches of a sloughing brachial artery with complete success, the patient making a perfect recovery. He pointed out that this method of treatment was merely an extension of the ordinary rule for the treatment of secondary hæmorrhage —viz., dealing with the vessel at the site of the bleeding—and that in the cases mentioned it was the only alternative to amputation of the limb. The method was more likely to be of use in the case of the arm than of the leg, owing to the freer collateral circulation.—Dr. W. J. S. Bythell read a paper, illustrated by lantern slides, upon the Radiography of Renal and Ureteral Calculi. The paper dealt chiefly with the differential diagnosis between shadows due to calculi and those caused by other objects, such as calcareous glands. Examples were also given to show the advances made in x ray work, whereby it is possible to distinguish the size and structure of the kidney itself, and thus to a large extent make out the pathological condition of that organ. Such cases included several of pyonephrosis and tuberculous kidney.—Dr. George Ashton made a short communication on the Hypodermic Injection of Atropine and Strychnine in Chronic Alcoholism. He had tried this treatment in three cases, all confirmed alcoholics. The solution used was a mixture of liquor atropinæ sulphatis and liquor strychninæ hydrochloridi in the proportions of 1–4. Five minims of this solution were injected twice daily into the outer surface of the calf of the leg. The first patient had 70 injections, the second had 34 injections, and the third 30 injections. The general health was considerably improved, but the underlying disease—the craving for alcohol—was unaffected. His patients strongly objected to the repeated pain of the injections and to the dryness of the mouth caused by the atropine. Dr. Ashton had reluctantly come to the conclusion that the treatment was absolutely useless.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 7th, Dr. P. Boobbyer, the President, being in the chair.—Mr. A. M. Webber read a paper on Ante-partum Hæmorrhage. In this he classified the causes under injuries of the genital tract, disease of the cervix or vagina, and separation of the placenta. The last cause of hæmorrhage was again subdivided into accidental or unavoidable according to the implantation of the placenta. All these causes were illustrated by cases, Mr. Webber carefully reviewing the treatment of placenta prævia and urging the value of antiseptic douching in addition to the usual precautions against maternal sepsis. The paper was discussed by the President, Dr. J. H. Thompson, Mr. T. Geraty, Dr. W. Tibbles, Dr. A. J. Sharp, and Mr. W. B. Blandy, and Mr. Webber replied.—Dr. C. H. Cattle showed a woman, aged 29 years, the subject of Diffuse Scleroderma, a sequela of influenza four years previously. The whole of the upper half of the trunk, with the exception of the hands and backs of the elbows, was affected, as well as the head and neck.—Dr. F. H. Jacob showed the Characteristic Spectrum of Methæmoglobinæmia occurring in an elderly patient as the result of taking phenacetin to excess; and also a skiagram of the Pelvis and Hip-joints in an obscure case of Double Abnormality of the Cervix Femoris.—Mr. Webber showed a Heart with Patent Septum Ventriculorum fatal at the age of eight years in a boy. The kidneys from this case were also shown and were in a state of advanced pyelonephritis as the result of congenital stenosis of the meatus urinarius.

Reviews and Notices of Books.

Oxford Medical Publications: Diseases of the Spinal Cord. By R. T. WILLIAMSON, M.D. Lond., F.R.C.P. Lond., Assistant Physician, Royal Infirmary, and Lecturer in Medicine, Victoria University, Manchester. With 183 illustrations and 7 plates. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 432. Price 15*s.* net.

IN a subject so complex as neurology, to which additions are almost constantly being made from the results of physiological, pathological, and clinical research, there is always room for a book of reference in which the subject, or some branch of it, is considered in a manner more catholic and exhaustive than is necessary for a student's text-book and in which the results of recent work can be set forth and discussed. Dr. Williamson has devoted special attention to diseases of the spinal cord, and in the book before us, although he modestly disclaims any intention of furnishing an exhaustive account of spinal diseases, he has supplied in a manner wholly admirable a very thorough and suggestive consideration of them. He devotes special attention to the physiology and pathology of these conditions and these aspects of his subject are very well and liberally illustrated.

The structure of the spinal cord is described in some detail, and an interesting account is given of the blood-supply of the cord and of the relation of spinal diseases to the distribution of the blood-vessels. Some useful diagrams are given showing the parts of the cord supplied by the various arteries. The general pathological histology of the spinal diseases is next dealt with, and the various forms of degeneration, chromatolysis, and other changes occurring in the nerve elements are described clearly and fully, while the conditions under which they occur are enumerated. The tracts of ascending and descending degeneration are carefully described and figured, and their origin, course, and functions are discussed so far as these are known. Under this heading some of the tracts which are less generally known are included, such as v. Monakow's, Helweg's, and Hoche's bundles, Flechsig's oval field, and the triangle of Gombault and Phillippe. The functions of the spinal cord are considered at some length, and a careful and critical summary is given of the various views at present put forward in regard to the vexed questions of the paths of conduction of the different forms of afferent impressions and of the crossing of sensory fibres. The views of Edinger, Gowers, Sherrington, and Head and Thompson are given. The reflex, trophic, vaso-motor, and visceral functions of the cord are similarly dealt with.

A useful section is devoted to a general consideration of the symptoms of diseases of the spinal cord. These are classified into motor, reflex, sensory, and trophic symptoms, paralysis of bladder and rectum, and ocular symptoms. Each is described in detail, the methods of eliciting it are set forth, its indications and the conditions in which it occurs are then enumerated. The author incorporates not a few original observations in this section. The account given of the reflexes may be mentioned as of special interest. The tendo Achillis jerk is stated to disappear sometimes before the knee-jerk in conditions in which the latter is usually lost—e.g., in tabes, general paralysis of the insane, peripheral neuritis, diabetes mellitus, and in alcoholic heart failure. The vibrating sensation as tested by a tuning-fork, of which the foot is placed over subcutaneous bony prominences, is also described at some length, and is regarded as a delicate test for detecting slight impairment of sensation. Electrical examination and the uses of lumbar puncture are considered in a separate section. In relation to the reaction of degeneration, Dr. Williamson lays stress upon the sluggish and prolonged contraction of degenerated muscle as contrasted with the sharp and short contraction in the normal state. The diagnosis and localisation of diseases of the spinal cord are carefully and clearly discussed. Useful tables of motor localisation and sensory distribution are given for purposes of anatomical or topographical diagnosis. General rules are also given to assist in forming the pathological diagnosis. The effects of unilateral and complete transverse lesions are described, and the characters of Brown-Séquard's paralysis are set forth. The question of the state of the reflexes in complete transverse lesions is critically considered, and the general conclusion arrived at is that while the condition of absent reflexes and flaccid paralysis described by Bastian is the rule there are exceptions.

The general classification adopted by Dr. Williamson is into four clinical groups—viz., diseases in which the prominent symptoms are those of a transverse lesion of the cord, of atrophic paralysis, of spastic paralysis and of ataxia, and a section is devoted to each of these. The classification is a convenient one and saves a considerable amount of repetition. In the first of these groups the various conditions to which the term myelitis is applied are considered and differentiated from one another. Compression myelitis is described in a most thorough and careful manner, and great stress is laid upon the necessity for careful examination of the spine in all cases of lateral sclerosis of obscure nature. In this same section the subjects of spinal tumours and spinal cysts are discussed in a most thorough manner, and the account is one of the best with which we are acquainted. The description of the symptoms of lesions of the cauda equina and conus terminalis is also worthy of special mention, and the diagnosis of these conditions is carefully discussed.

The next section deals with diseases causing atrophic paralysis and includes the various forms of acute, subacute, and chronic poliomyelitis, progressive muscular atrophy, amyotrophic lateral sclerosis, and syringomyelia. In connexion with the pathology of progressive muscular atrophy, Dr. Williamson records a case in which the symptoms were typical of the Aran-Duchenne type, and in which death occurred 22 years after the onset of the disease. Neither on clinical examination nor after careful microscopical examination after death was there any evidence of amyotrophic lateral sclerosis, and therefore he regards the two conditions as separate diseases or distinct forms of one affection, in opposition to the contention of some authorities that there is no distinction between these conditions and that they own a common pathological basis. At the same time he admits that the clinical diagnosis of progressive muscular atrophy cannot be an absolute one since features of amyotrophic lateral sclerosis may supervene at a later date, and further, that cases apparently typical of progressive the employment of massage and of electricity. Hydrotherapy is also most efficacious while drugs he holds should be used only as a last resource.

There is, as we have said, a good deal of repetition in this work, and it is unduly bulky, but Dr. Bandler has succeeded in carrying out his intention and the student will find in the book a very fair representation of the most approved and modern methods of the medical treatment of gynæcological cases. The illustrations are not of any particular value. There is a fair index.

Précis de Stomatologie. By J. REDIER Vol. I. Paris: F. R. de Rudeval. 1909. Pp. 542. Illustrated. Price 5 francs.

THE ground covered in this volume includes the development and anatomy of the teeth, abnormalities of the teeth, the complications of dentition, and caries of the teeth. On reading the book we cannot help feeling that if an international nomenclature of dental diseases existed a large amount of misunderstanding would be avoided. Take, for example, the use of the term erosion; in this country and in America the term is limited to a progressive destruction of the tooth tissue due in many cases to abrasive agents; in France the term is used to describe defects of the teeth arising from constitutional causes and usually known in this country as hypoplasia of the teeth—in other words, two totally dissimilar lesions are described by a similar term. Throughout the book the author has adopted with success plain line diagrams instead of more elaborate illustrations in describing models of the teeth and appliances; he has only had recourse to more detailed drawings in describing histological sections, and the technique of these is excellent. The author discusses very fully the etiology of caries under the headings of extrinsic and intrinsic causes, but he adds little to what is already known. He places considerable importance on the influence of the race in relation to the incidence of caries and strives to show that in France it bears a relationship to the distribution of the early races. He seems, however, to lose sight of the fact that races differ considerably in their food and habits, and in that difference may possibly be found an explanation of the figures which he quotes. The book is, we consider, well worthy of perusal and does credit to its author.

LIBRARY TABLE.

An Atlas of Skiagrams Illustrating the Development of the Teeth, with Explanatory Text. By JOHNSON SYMINGTON and J. C. RANKIN. London: Longmans, Green, and Co. 1908. Price 10*s.* 6*d.* net.—This series of skiagrams is a systematic attempt to examine by means of the *x* rays the position and relation of the teeth at different stages of development. The skiagrams have been taken from 18 children, whose ages at death ranged from nothing (i.e., who died at birth) to 16 years, and from one adult, and the series forms a fairly complete history of the calcification of each tooth. The method adopted in investigating the specimens was to divide the head on the median plane and, as a rule, remove all the soft tissues, except the muco-periosteum of the jaws; the specimen was then placed on a photographic plate with the posterior part of the head raised about 30 degrees above the horizontal plane. By these means the shadows of the teeth at the front part of the dental arch were to a great extent avoided. The authors have by these means produced a really excellent series of skiagrams, 23 in number; each specimen is accompanied by an explanation, and in addition five drawings are added showing the maxillary sinus at different ages. An examination of the plates brings to light one or two points of interest in connexion with the calcification of the teeth. In the first place, it appears quite clear that the first permanent mandibular molar commences to calcify at an earlier period than the corresponding upper teeth and that the only portion of these teeth calcified at birth is the anterior lateral cusp of the lower tooth. Development of the permanent incisors and canines would seem to commence at an earlier period than usually stated, for the authors could detect them in skiagrams from infants four and a half months old. Another point worthy of notice is that calcification of the third permanent molar does not commence until after the ninth year and that the growth of the upper tooth is in advance of the lower one. In considering how far the results shown in these skiagrams should be taken as authoritative it must be remembered that the dental arch in all the specimens was not normal; no history as to the cause of death is given; still further the amount of material investigated is far too small. By these remarks we do not wish in any way to disparage the excellent work the authors have done, and we only hope that they will carry their investigations further and place us in possession of absolutely trustworthy data on the development and calcification of the teeth.

Handbook for Attendants on the Insane. Published by the authority of the Medico-Psychological Association. London: Baillière, Tindall, and Cox. 1908. Fifth edition. Pp. 390. Price 2*s.* 6*d.* net.—This is a new and revised edition of a widely known handbook. It has been found, according to the preface, that in certain places the training already given has developed a strong demand for some advanced teaching. The scope of the book has therefore been enlarged and we cannot but feel that it has been over enlarged. It appears to us that much that is now included in the handbook tends to make it much more than a handbook for attendants, and indeed has caused it to become a somewhat inadequate textbook. If there is, in fact, a demand for advanced teaching we think it should be met by recommending the perusal of some of the excellent manuals of morbid psychology with which the libraries of asylums are supplied, rather than by attempting to pad out a book for beginners with matter which, for its proper explanation, requires considerably more space than can, in the circumstances, be devoted to it. Many of the descriptions of symptoms given are good and the advice as to the general care and nursing of the insane is excellent, but the book, as a whole, requires more careful editing than it has received.

THE CHURCH MISSIONARY SOCIETY.—One of the special features of the great missionary exhibition, entitled "Africa and the East," which will be held at the Royal Agricultural Hall, from June 8th to July 3rd, under the auspices of the Church Missionary Society, will be a special exhibit of outfit suitable for missionaries and travellers which will be shown in a special outfit section. This section is being arranged under the auspices of Livingstone College, which is specially devoted to the study of all questions affecting the health of missionaries, and in the years 1900 and 1901 organised an important outfit exhibition at the St. Martin's Town Hall and Westminster Town Hall respectively. It is hoped on the present occasion to demonstrate the most up-to-date methods of modern outfitting for travellers in the tropics, and the leading firms who provide articles for missionary equipment are being invited to take part in this section. One of the special features of this section will be an exhibition of the various methods of protection from mosquitoes and other insects, which, it is well known, play an important part in the spread of many tropical diseases. It is often difficult to impress upon people's minds the great importance of the outfitting problem in its relation to health, and this section will, it is believed, prove of interest to many who would not ordinarily be attracted by a missionary exhibition. The organiser of this section, Dr. C. F. Harford, Principal of Livingstone College, will be pleased to communicate with any who desire particulars concerning it if they will write to him at Livingstone College, Leyton, E.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1909.

The Children Act.

A LITTLE more than a year ago we commented briefly in a leading article[1] on the general scope and aims of the Children Bill, and we then expressed the hope that so important a measure might be raised above the storms of party strife and secure speedy enactment. The instinct of parental care is so fundamental in almost all the higher forms of animal life that it might have been expected that in man, owing to the development of the altruistic sentiment, the general care of infant life and the adequate nurture and education of children would have been among the earliest matters to receive attention in a progressive civilisation. It is hardly to the credit of our sociological evolution that the collective study of child life is of such recent development, while the widespread disregard which has been shown to exist in regard to the most elementary principles of hygiene as applied to infants and children, and the wholesale loss of infant life which the mortality tables show as a result, are among the greatest stains upon our boasted progress. It is, however, gratifying to find that the general awakening to the importance of these questions in relation to the national weal has resulted in the welcome accorded by all sections of Parliament to the Bill which has now taken its place upon the Statute Book. Its provisions came into operation on April 1st, and the present is therefore an opportune moment to consider, especially in regard to their medical and hygienic aspects, some of the more important of the sections of this Act, which has not inaptly been called the Children's Charter, inasmuch as it gives greatly enlarged powers to certain authorities with mechanisms for enforcing them, and is designed with a view to ameliorate in every way possible the conditions of life in infancy and childhood.

Of the six parts into which the Act is divided the first two, those dealing with Infant Life Protection and with the Prevention of Cruelty to Children and Young Persons, are those with which we are more especially concerned. In regard to the important subject of Infant Life Protection the Act marks an advance upon the Act of that name passed in 1897, in that it renders subject to inspection *every* infant who is placed out to nurse for more than 48 hours for fee or reward, whereas the Act of 1897 only dealt with foster parents who received more than one infant under the age of five years, the age limit being also raised in the present Act to seven years. An important provision of this section is that every infant under that age who is put out to nurse for more than 48 hours must be notified by those in charge to the local authority, which is defined for the county of London as the County Council, for the City of London as the Common Council, and elsewhere as the guardians of the Poor-law Union. The foster parents must further notify these local authorities within 48 hours of any change of residence, and also of death or removal of the infant, and in the latter case must also state the name and address of the person to whom the infant has been transferred. They must also inform the coroner within 24 hours in the case of death of an infant under their care. They are not permitted to insure the life of any such child, and insurance companies are forbidden to accept any proposal for such insurance. The local authorities have the power to fix the number of infants which may be kept to nurse in any one building, and they are required to appoint one or more persons of either sex to act as "infant protection visitors," whose duties include the visiting of infants registered with the local authorities, in order to satisfy themselves as to the proper nursing and maintenance of the infants or to give advice or directions in regard to these matters. They may obtain search warrants from a justice if refused admission to any premises and can order the removal of an infant if they find the premises are overcrowded, dangerous, or insanitary, or if they find evidence of negligence, ignorance, inebriety, immorality, criminal conduct, or other similar cause.

The second part of the Act, that dealing with the prevention of cruelty to children and young persons, contains some provisions important to medical men. Among the most important is that which provides penalties for any person over the age of 16 years who has the custody, charge, or care of any child, and who either directly or indirectly assaults, illtreats, neglects, or exposes such a child in a manner to produce unnecessary suffering or injury to his health. The penalties on conviction on indictment may be a fine not exceeding £100 or imprisonment with or without hard labour for a period not exceeding two years, unless it can be shown that the person convicted was financially interested in the death of the child, when the fine may be increased up to £200 and the term of imprisonment extended to five years' penal servitude. It is specifically stated that failure to provide adequate food, clothing, medical aid, or lodging is to be deemed neglect in a manner liable to cause injury to health if the person having care of the child, being unable to provide these necessaries, fails to take steps to obtain appropriate relief from the proper authorities. A conviction under this section of the Act may be made even though actual suffering or injury to health was obviated by the action of another person. Dr. J. NIVEN, the medical officer of health of Manchester, in a report upon the Act prepared for the Infant Life Protection Committee of that city, points out the importance of the section which requires the persons, who are legally liable to maintain any child, to provide adequate medical aid, and has submitted for legal opinion the question as to whether this includes an obligation to carry out the instructions given by a medical practitioner. The reply received was that the carrying out of reasonable instructions (within the ability of the parent or guardian) would be included, in other words, a guardian of a child can not avoid his responsibility by consulting a medical man and then omitting to do as he is advised. Dr. NIVEN points out further that this section should afford great assistance to the education authorities since it will enable them to secure that parents shall provide medical aid in those cases in which the medical inspectors or school nurses have advised that it is necessary. But it is obvious that the effects of this section, if effectively carried out, will be very widespread, for it must include not only every case of neglect, whether through ignorance or as a result of wilful and deliberate cruelty or callous indifference, but also those in which failure to secure medical aid is the result of religious belief or sectarian tenets.

---

[1] THE LANCET, Feb. 15th, 1908, p. 507.

This section of the Act will also prove to be of value in regard to the spread of infectious diseases. Among the poor it is said to be not uncommon where one child is affected by a disease such as measles or whooping-cough to allow other children to sleep with the infected child and to neglect all precautions to prevent spread, on the misguided idea that to suffer from the disease is inevitable, and that it is as well "to get it over." Among the very poor segregation of the sufferer must be almost impossible in the home, but deliberate exposure of a child to the risk of infection might well be regarded as an offence under this section. It is also perhaps not too much to hope that eventually the Act may assist in lessening the terrible incidence of rickets upon the children of our large towns, since the health visitors, if such be appointed, may give instruction in regard to proper feeding or compel medical treatment where the disease is established. Other matters receiving special mention in this part of the Act are those of "overlaying" and burning or scalding. In the case of an infant under three years of age being suffocated while in bed with a person over the age of 16 years, who was at the time of going to bed under the influence of drink, this shall be deemed "neglect in a manner likely to cause injury" and be punishable accordingly. If a child under the age of seven years be left in a room containing an open fire-grate not sufficiently protected, and as a consequence is burned or scalded, the person responsible is liable to a fine of £10. In this connexion, although no mention is made of the danger of inflammable flannelette, it is to be hoped that in cases of burning from this cause a similar punishment will be enforced. A special part of the Act is devoted to the question of juvenile smoking and its prevention. This during the discussion of the Bill was the cause of no little amusement. It is of subsidiary importance but is one with which we cannot but agree. In the concluding part of the Act under the heading "General and Miscellaneous" it becomes an offence, punishable with a fine not exceeding £3, to give to a child under five years of age any intoxicating liquor, except upon the order of a duly qualified medical practitioner, or in case of sickness, or apprehended sickness, or for other urgent cause. A further provision is that a local education authority may enforce the cleansing of verminous children. The remaining sections of the Act deal with reformatory and industrial schools and juvenile offenders, and are outside the scope of our present comments.

We cordially welcome the measures for the enforced care of children and infants as regards their physical and moral health and well-being, for no one sees more clearly the results upon the young of our population of ignorance and neglect than the medical practitioner, who too often finds his best efforts stultified by wanton disregard or careless performance of his instructions. In the operation of some of its measures the Act must of necessity be experimental, and it is not easy to foresee in what manner and with what results some of its provisions will be administered, though it is to be hoped that the powers conferred upon the various authorities will be exercised with tact and discretion, but without laxity, and that where experience proves that modifications are necessary these may be made as speedily and effectively as possible. The Act marks an advance in the history of our civilisation and one that future generations may regard as one of the greatest advances, since its aims are purely humanitarian and its objects the betterment of the conditions of life of our population at the most vulnerable periods.

An Ambulance Service for the Metropolis.

WE regret to see that the Home Secretary, while acknowledging the ability and value of the recent report of the Committee appointed by his department "to inquire as to the provision made for dealing with cases of accident and sudden illness occurring within the streets and public places of the metropolis," holds out no hope of any immediate action on the lines recommended. The Committee was asked to report whether any, and if so what, improvements in ambulance provision are necessary or desirable in the metropolis, and was invited to say how reforms could be best effected with due regard to efficiency and economy. Its reply was the document, a very full abstract of which appeared in THE LANCET of April 3rd, which, while it showed over and over again that a properly organised ambulance service is required in the metropolis, left the Home Office choice of two directions in which to look for a proper authority over such a service. The majority—viz., two out of three of the Commissioners, the Earl of STAMFORD and Sir KENELM DIGBY—wished to constitute the Metropolitan Asylums Board, in coöperation with the Metropolitan Police, the authority over the new ambulance service; the Minority Report signed by Sir WILLIAM COLLINS upholds the claims of the London County Council. A choice of procedure is thus laid before those who make themselves responsible for future legislation, and this further is a little complicated by the undoubted fact that the report has gone outside the terms of reference and has taken into consideration the care not only of "cases occurring within streets and public places," but also of cases occurring on private premises. By including these last cases in the purview a sound argument results for making the Metropolitan Asylums Board the authority, for undoubtedly that Board might well take charge of such cases, receiving proper payment for services rendered. On this last point there ought to be no doubt, for it would be distinctly unfair to the public that firms, for example, where the business carried on makes a certain number of accidents an absolute certainty, should be able to obtain gratuitously the ministrations of a rate-supported organisation. In our view, however, these cases upon private premises did not come within the scope of reference of the Commissioners. When they occur they can be dealt with by medical men engaged in private practice in the ordinary manner, and if thought necessary by such medical men the ambulances of the Metropolitan Asylums Board can be *obtained on payment and the patients taken home or to hospitals as the case may be.* With the exclusion of these cases the particular fitness of the Metropolitan Asylums Board to act as an authority for a new ambulance service for the metropolis seems to us largely to disappear and the question resolves itself into one between the police and the London County Council.

Sir William Collins, in arguments which we have set out in our abstract of his memorandum added to the report, makes out a good case for the London County Council, and we are so far in accord with his view that we consider that the relieving of the police of duties so remote from their usual functions as the transportation of invalid and sick persons must commend itself to the framers of any legislation for many practical purposes. Moreover, we presume that the London County Council ambulance service would be worked by efficient and exactly trained attendants whose assistance in many cases might be more valuable than that usually afforded under the heading of "first-aid." On the other hand, we cannot fail to see that there is much to be said for the police undertaking the duty because it is, in the words of the report, "*the police who have the first responsibility for the safety of the patient on the happening of the casualty*," so that if the police do not have the responsibility throughout it must be divided somewhere with risks of friction or inefficiency. Omitting the Metropolitan Asylums Board from our consideration, we wonder whether it will be possible for the police and the London County Council to coöperate in some satisfactory manner, and it is in this direction that we should almost anticipate a working plan were it not a direction which the able Commissioners have not taken. To medical men, however, the great thing is action in some direction. Probably under any of the three authorities suggested, or under any of the *four* possible combinations of them, a sound scheme could be devised which would remove from the metropolis a reproach under which it now lies. We hope that temporary pressure in Mr. Gladstone's department will not result in any long shelving of a matter of vital interest to the public.

◆

The Pathology of Epilepsy.

The clinical phenomena in association with epilepsy are universally recognised, but the pathology of the disease has not yet been satisfactorily explained. There are no *gross* lesions to be found in the brain after death from epilepsy and the microscopical changes cannot be said to be characteristic. It has been assumed by some observers that injury to the neurons occurs or that there is some alteration in the chemical constitution of the grey matter; as a result sudden liberation of nerve energy in the grey matter of the cerebral cortex takes place without being excited by the normal stimulus. Sir William Gowers has suggested that the liberation of nervous energy involves the escape of some atoms of the nerve tissue which are at once replaced from the plasma adjacent to them under the mysterious nutritional influence of life. "The rearrangement is the same and yet not quite the same." It differs in just the degree and character to make the same release of nerve energy more easy; it is this recurring tendency he maintains that constitutes the disease. Regarded from this point of view epilepsy must practically be set down as a functional affection. In the Goulstonian lectures delivered before the Royal College of Physicians of London, which have been fully reported in our columns,[1] Dr. A. E. Russell brings forward some able arguments in attempting to show that the pathological condition which gives rise to epilepsy is anæmia of the brain. Others have suggested cerebral anæmia as the pathological factor in epilepsy, but in these lectures the full facts supporting this theory are fully and clearly set forth. Dr. Russell's remarks are characterised by lucidity and thoughtfulness and are worthy of close attention and study.

The title selected for the lectures was "Some Disorders of the Cerebral Circulation and their Clinical Manifestations" Dr. Russell first drew attention to syncopal attacks which may ensue when there is a diminution in the volume of blood passing through the brain. He pointed out that a sudden depression of the normal vaso-motor tone in the splanchnic area leads to a rapid accumulation of blood in the capacious vessels of that region; if only momentary in duration the result is merely the sudden sinking sensation experienced at the pit of the stomach, so common after any unexpected noise or fright. If of longer duration this preliminary sensation or aura is succeeded by a faint. He next proceeded to describe a type of attack in which vagal and vaso-motor symptoms are prominent and in which consciousness, though modified, is not of necessity lost. These cases exhibit obvious changes both in the cardiac and systemic systems, and vaso-dilatation in the splanchnic area is almost beyond dispute in many of these instances. Occasionally a fainting fit is preceded by definite subjective sensations or auræ, and the lecturer quoted Sir William Gowers, who has recorded cases in which repeated syncopal attacks passed into epilepsy. In some attacks of syncope there is marked cardiac and vascular instability with the development of a series of symptoms depending on these cardiac and vaso-motor changes; and many of these symptoms are identical with epileptic auræ, though more prolonged. The degree of consciousness preserved by the patients also varies; in some it is only modified, in others it may almost vanish, and in others complete unconsciousness may develop. The next step in Dr. Russell's arguments was the production of evidence to show the occurrence of cardiac arrest in idiopathic epilepsy. He referred to a case which he himself had observed in which at the commencement of an epileptic attack there was a temporary arrest of the heart's action, and other similar instances have been recorded. The cardiac arrest may, he submitted, be due to vagus inhibition of the heart and may be brought about by a widespread vaso-constriction. There is no doubt, he holds, that in epilepsy the vaso-motor system is unstable and an irregular pulse is frequently met with in epileptic patients. Having shown that there is evidence in favour of a derangement of the cerebral circulation at the time of an epileptic fit, Dr. RUSSELL maintained that this circulatory failure offers a more reasonable explanation of the phenomena of the disease than any hypothesis yet brought forward. He reminded his hearers that a partial cerebral anæmia has been demonstrated by Dr. LEONARD HILL to be capable of giving rise to the symptoms of an epileptic aura; also that in the condition of heart block, in proportion as the period of cardiac asystole increases, varying degrees of cardiac failure manifest themselves, producing transient unconsciousness indistinguishable from that of *petit mal*, or attacks with very temporary spasm, or finally definite epileptic fits. Dr. RUSSELL also supported his contentions by a brief consideration of uræmia. In this condition the blood pressure is considerably raised and the intracranial pressure is necessarily high. Working against this strain the heart may fail rapidly in chronic nephritis. Should this occur, or should the vaso-motor centre fail rapidly, it is clear that the cerebral circulation must also be affected and a state of anæmia be produced. Hence there is much force in Dr. RUSSELL'S contention that the pathology of the cerebral manifestations of uræmia is to be sought in disturbances of the circulation through the brain. Finally, the lecturer quoted Dr. F. W. MOTT, who has shown that the essential changes in the brain in cases of status epilepticus are (1) great venous congestion and stasis; and (2) œdema of the brain and marked distension of the perivascular lymphatics with flattening of the convolutions and increased vascularity visible to the naked eye. Inasmuch, however, as the brain is contained in a closed cavity, venous stasis and œdema must be associated with a corresponding arterio-capillary anæmia.

---

[1] The Lancet, April 3rd and 10th, and p. 1093 of the present issue.

It will be seen that in his lectures Dr. RUSSELL maintained that the fundamental factor underlying both the ordinary faint and the epileptic fit is cerebral anæmia. He also stated that the difference between the two is one of degree rather than of kind. Dr. LEONARD HILL, however, has pointed out that no evidence has been forthcoming of any independent change pointing to the existence of any vaso-motor nerves supplying the brain. Dr. HILL states[2] that no positive proof of vaso-motor changes in the brain has appeared on stimulation of the vaso-motor centre, the central end of the spinal cord after division of the cord in the upper dorsal region, or on stimulation of the stellate ganglion. Further, he holds that no conclusive evidence has been produced of the existence of any local vaso-motor mechanism such as might be called into play by the injection of drugs into the cerebral circulation. Upon the knowledge hitherto accepted of the physiology of the cerebral circulation it would seem to follow from these considerations that the cause of fainting as well as of the epileptic fit lies outside the brain. With the fainting fit there is no difficulty in admitting the supposition, but with the epileptic fit there is naturally some hesitation in at once accepting circulatory disturbances commencing outside the brain as the true pathology of epilepsy. As an answer to this objection it is worthy of note that Dr. RUSSELL mentions the fact that a copious network of nerve fibres to the cerebral blood-vessels has recently been demonstrated. From a histological point of view this is valuable testimony in favour of his suggestions, and if physiological proof is also forthcoming the objection we have raised is weakened. There is another point, however, which he did not refer to—namely, the effect of drugs on the course of epilepsy. One of the most useful remedies in preventing the onset of the attacks is bromide of potassium. The main action of this drug is to allay excitability and irritability, but in persons under the influence of the drug venous stasis is liable to occur, probably due to the weakened condition of the heart, and perhaps also to an impaired tone of the vaso-constrictor nerves. Relaxation of the arterioles would allow more than the normal quantity of the blood to remain in the mesenteric and cutaneous vessels and would thus aid in the production of anæmia of the brain—the very condition it is desired to combat, according to the circulatory theory of the production of epilepsy. We shall look forward with interest to the further developments of the views so admirably laid down by Dr. RUSSELL. We congratulate him on having given to the profession a most useful course of lectures. In so doing he has upheld the wisdom of Dr. GOULSTON in founding the lectureship which he directed should be allotted annually to one of the "four youngest doctors in physic" of the College. The original work accomplished by those nominated to give the lectures each year has proved valuable to the progress of medicine, and the lectures delivered this year are worthy successors of those that have preceded them.

Annotations.

"Ne quid nimis."

THE RISKS OF THE LOCAL INOCULATION OF TUBERCULOSIS.

THE importance of the danger of the dissemination of tubercle bacilli by means of the sputum is known not only to the medical profession but also to the public, but it is not sufficiently appreciated that the saliva is also a possible medium of contamination. It is not only possible, but certain, that the saliva of patients affected with pulmonary tuberculosis is capable of conveying the disease, and on another page of this week's issue of THE LANCET is published an important paper on this point by Dr. Newman Neild and Dr. E. V. Dunkley. They show, in the first place, that in a large proportion of cases of phthisis tubercle bacilli can be found in the saliva, especially shortly after expectoration. In the second place, they were able to demonstrate by examining bacteriologically the flaps of envelopes which had been fastened by consumptives that in one case out of two tested tubercle bacilli could be found. Saliva plays an important part in the practical life of many people. It is looked upon as a providential arrangement for the provision of small quantities of liquid whenever required, and its ready availability has no doubt much to do with the extent of its employment. With saliva most people affix stamps to letters, even if from doubt of the cleanliness of the gum of the stamp, or from dislike of its taste, the letter is licked and not the stamp. Envelopes with embossed stamps on them save this necessity, but the envelope flap has still to be moistened and the tongue is the appliance usually employed. Moisture certainly favours the marking powers of a lead pencil, and here again the saliva is called into use. To turn over the leaves of a book moist fingers are found to be effective by not few uncleanly and barbarous persons, and the mouth is usually the readiest source of moisture. Should someone else use that pencil or that book the risk of the conveyance of micro-organisms from the first user to the second is by no means small. It will be remembered that in the "Arabian Nights" the contamination of the moistened fingers employed to turn over the leaves of a book is employed to poison an unjust king, and perhaps the episode was set down for our instruction—to warn us against a nasty trick. A school slate is happily becoming a thing of the past for several reasons, but the facility with which the tongue of the child served to erase the writing on the slate was very liable to lead to infection. Lastly, saliva is frequently employed for what may be euphemistically termed ablution, and though the practice is mainly prevalent amongst the lower classes, yet it is not unknown elsewhere, and as the victims are generally children there is little doubt that such ablution is widely used by nursemaids on the children they have to tend. Several other equally objectionable methods of employment are mentioned in the paper to which we have referred, and the conclusion at which we must arrive is that the use of saliva for anything else than for its digestive functions is very likely to disseminate disease. This *a priori* opinion is fully supported by a large amount of evidence of actual inoculation of tubercle by the saliva of phthisical persons. In some cases the patient inoculates himself, as when a woman with consumption applied her saliva to an irritating eruption on the arm, and at the site arose some lupus nodules. In such a case as this inoculation is especially likely, for the soil is suitable for the growth of the tubercle bacillus. In most of the cases, however, the patient is inoculated by means of the saliva of someone else. In piercing the lobule of the ear so as to permit the wearing of earrings the saliva of the operator is often employed to lubricate the needle, and from this source or from the use of the saliva as a styptic the appearance of a tuberculous nodule at the opening made is not very rare. In the performance of ritual circumcision it was the custom not long ago for the operator to stay the bleeding by sucking the wound, and though the practice is given up by the more educated mohelim, yet the primitive method is highly appreciated by a section of the Polish Jews. This practice has in many cases given rise to a local inoculation of tuberculosis. In some cases a tuberculous ulcer has appeared on the prepuce and in others the inguinal lymphatic glands have broken down. The objectionable procedure giving rise to these unfortunate cases is certainly less prevalent than formerly and it is to be hoped that it will die out entirely as the general level of education rises. Another mode of infection through the saliva of a tuberculous person is to be found in tattooing. Apart from mere sepsis, syphilis is the most frequent form of specific infection resulting from tattooing, but tuberculosis also occurs. Jadassohn's case is typical. A healthy woman, aged 30 years, was tattooed on the forearm by a consumptive man who afterwards died from phthisis. The Indian ink used for the tattooing was moistened with the man's saliva and typical lupus nodules developed on the tattooed patches. In tattooing the needles are often also moistened with saliva. It is clear that however convenient it may be to employ saliva for these manifold uses it is eminently desirable that such practices should cease, for they have been proved to be the means of conveying infectious disease in many instances, and we are fully justified in thinking that infection occurs by this channel in many cases in which no suspicion of it arises. The practice of licking stamps and envelopes should be done away with. When sealing a letter with wax was considered to be the correct method it was looked upon by many as an insult to have a letter fastened by a wafer sent to them, for as it was on one occasion somewhat crudely expressed, "Why should this man send me his spittle?" To say the very least of it, the promiscuous use of saliva is wanting in refinement, and, as the paper by Dr. Neild and Dr. Dunkley has shown, it is wanting in sense, for it introduces a quite unnecessary risk of microbic infection into our daily intercourse.

SPRING CLEANING.

SPRING-CLEANING, especially when certain simple precautions in carrying it out are not observed, is not without its obvious possibilities for evil. The cardinal fact connected with this procedure is that there must always be potentialities for evil lurking in dust and dirt, and a general house cleaning means the removal of these deposits which usually represent the sum of a year's accumulation. It would be strange indeed if this accumulation was free from disease-producing organisms, and it never is. Bacteriological examination would be bound to reveal a rich garden of pathogenic entities in the household dust and dirt annually removed in the spring cleaning process. It follows that only that method of spring cleaning can be approved which secures the removal of the dust and dirt as against one which merely scatters them. Spring cleaning, after all, amounts to the application of aseptic principles to the dwelling-house, and modern refinements teach that unless the process is well done it might as well be left undone. The accumulation of dirt in a house is repugnant to sanitary ideas, but the process of cleaning should not be an annual ceremony but one carried out at more frequent intervals. Few householders, however, would find it convenient, we imagine, to submit the house to a kind of aseptic process more than once a year, and yet the fact that it is commonly done only once means that an accumulation of some depth and intensity has to be dealt with. Theoretically, no materials that may probably contain dormant disease-producing entities should be allowed to accumulate their forces, and therefore spring cleaning as an annual aseptic process applied to the house is wrong in principle. According to this view spring cleaning should be abolished in favour of a regularly conducted cleaning process kept up all the year round at comparatively short intervals. This is the course pursued by many careful citizens nowadays and the public would do well to follow their example.

ECLAMPSIA OR CEREBRAL HÆMORRHAGE.

THE occurrence of convulsions in pregnancy due to eclampsia is so much more common than any other variety of convulsive seizure that the practitioner is tempted to diagnose eclampsia at once in any case in which a pregnant woman has a fit. When we recall the fact that cerebral hæmorrhage occasionally complicates cases of eclampsia it is not surprising to find that the diagnosis between these two conditions may present great difficulties. Small meningeal hæmorrhages are, of course, not uncommon in cases of eclampsia and are usually attributed to the rise of blood pressure produced by the fits, and in accordance with this view they are most frequent in cases where a large number of convulsions have occurred. Cases of the apoplectiform eclampsia of the older writers characterised by large hæmorrhages into the brain substance are by no means so common, but do occur from time to time, and by masking to a large extent the symptoms and physical signs due to the eclamptic condition may render a certain iagnosis impossible. Dr. Alan Randle records a case in he present issue of THE LANCET, p. 1111, which is a good lustration of this difficulty. The patient, 43 years of age, multipara six months pregnant, was thought to be suffering from eclampsia, but at the post-mortem examination was ound to have a large cerebral hæmorrhage filling both entricles and extending to the medulla, the patient dying om respiratory failure. The urine contained a considerable uantity of albumin, but there was no paralysis or true næsthesia. The kidneys were of the red granular type, he liver was congested, and the heart was hypertrophied. he patient had suffered from lassitude and headache or ten days, but there was no history pointing to ny previous renal trouble and there was no œdema. he was confined of a six months' partly macerated œtus, and as the condition improved after her delivery he diagnosis of eclampsia was thought to be confirmed. t is very probable that not a few of the cases of so-called clampsia without fits may in reality be instances of cerebral æmorrhage simulating eclampsia. Among the more striking eatures, as N. C. Carver and J. S. Fairburn have pointed ut,[1] in cases where eclampsia is complicated by severe erebral hæmorrhage, especially when it involves the pons, s the youth of the patients, the absence of any fit, or the occurrence of only one or two followed by the onset of deep oma with respiratory stertor and in many cases Cheyne-Stokes breathing. A correct diagnosis is of the utmost mportance if an accurate prognosis is to be made, but only oo often the cerebral hæmorrhage is only discovered at a post-mortem examination, and in such cases the question as to whether the case is one of pure cerebral hæmorrhage or cerebral hæmorrhage complicating eclampsia will depend on the discovery of the characteristic lesions of eclampsia in the kidneys and the liver. Luckily, cases of extensive cerebral hæmorrhages, contrary to the general opinion, are in reality rare in eclampsia; thus in 216 cases collected by various writers in only seven did there appear to have been any large cerebral hæmorrhage. In an attempt to arrive at a correct diagnosis of eclampsia in a comatose patient stress must be laid on the previous history, the age of the patient, usually a youthful primipara, the discovery of a large quantity of albumin in the urine, the presence of œdema, the absence of hemiplegia or rigidity in the limbs of one side, and the occurrence of repeated convulsions. It is obvious that where a large area of the brain substance is destroyed by the hæmorrhage the diagnosis, as in Dr. Randle's case, may present almost insuperable difficulties, and it must be borne in mind that in some cases of hæmorrhages into the pons convulsions are not uncommon.

OVERCROWDING ON THE DISTRICT RAILWAY.

IT is a commonly expressed opinion that what are called facilities for locomotion lessen overcrowding both in the conveyances themselves and in the streets. As a matter of fact, the exact opposite seems to be the case as regards London. The discomfort and in some cases the dangers of overcrowding trains and the like have of recent years become notorious, and it cannot be wondered that numerous questions are asked in Parliament on the matter. On April 6th various members of the Labour Party attacked the Metropolitan District Railway Company on account of overcrowding. Mr. C. W. Bowerman pointed out that the overcrowding took place at morning and night, which is an undoubted fact. Mr. W. Thorne, on the other hand, argued that a great deal of the overcrowding happened in the middle of the day, because fewer carriages were run. Mr. H. J. Tennant, on behalf of the Board of Trade, promised to make representations. That overcrowding does exist is indubitable, but it is just as obvious and just as annoying upon the municipally owned tramcar as on the capitalist railway carriage. As the "thousands of working men and women," to whom Mr. W. Hudson, the Labour Member for Newcastle, referred upon the same occasion, to say nothing of a few thousand more persons to whom he would not grant the title of working man, all have to get to their work between the hours of 5 A.M. and 10 A.M., and all strive to get home between 5 P.M. and 8 P.M., we do not see how overcrowding is to be averted. The modern body politic is just as complicated as the natural body, and all these difficulties are part and parcel of modern industrialism. When the worker lived over his shop or the rich tradesman had a few apprentices who lived in the house, while the journeyman lived only a few doors away, the need for travel did not exist. But under modern conditions no one in a great city lives near his or her work. Moreover, a great part of the overcrowding is due to pleasure-seekers and the hordes of surburban dwellers who come up for "sales" and theatres. It is evident from a remark of Mr. Thorne, "Are railways run for shareholders only," that the outcry against overcrowding on railways is not solely due to anxiety in the interests of passengers, but is partly inspired by the wish for the nationalisation of railways. But the state in London of the municipally owned tramcar forms a poor argument in this direction. At present there would appear to be no remedy, although such a state of matters is both dangerous to life and injurious to health.

RUPTURE OF THE ŒSOPHAGUS.

WOUNDS and ruptures of the œsophagus are by no means common. Phthisical patients occasionally rupture the œsophagus and in inveterate alcoholics constant vomiting sometimes results in the walls giving way. Of course, also, injuries to the neck may, though they very rarely do, involve the œsophagus. What is probably an unique case of rupture by violent distension has recently occurred in Sweden, which is reported by Dr. G. Petrén, assistant in the clinic of Professor J. Borelius in the University of Lund. The patient was a vigorous, healthy man, 27 years of age, who was employed as a cleaner and working by means of compressed air conveyed through an indiarubber tube. As he wished to move he doubled up the tube with his hands and seized the end between his teeth. While doing so he slipped and lost his hold on the tube which delivered its contents at a pressure of seven atmospheres directly into his mouth. He fell down complaining of a severe pain in the chest and vomited a small quantity of mucus tinged with blood. Three hours afterwards when admitted to hospital the neck, the integuments of the thorax, and the chin were emphysematous, the pulse was small, rapid, and irregular, respiration painful, and the general aspect very bad. The pain was referred to the epigastrium. The man could not stand or lie down but had to keep a sitting posture. A few hours later the emphysema had encroached on the face, the eyelids, and the arms. The dyspnœa became more and more pronounced and the heart's action grew weaker and weaker, death occurring the next morning. At the necropsy a vertical clean rent in the œsophagus was found 6 centimetres in length, the upper extremity being 1·5 centimetres from the bifurcation of the trachea; the surrounding connective tissue was infiltrated with pus. Thus the rupture in this very special case occupied the same position as ruptures due to vomiting generally do—that is, the lower end of the œsophagus, sometimes even involving the cardia. They are generally longitudinal and present clean edges as if cut with a knife, and they are generally situated on the posterior or lateral aspect of the œsophagus. If a diagnosis could be made sufficiently early it is quite conceivable that operative interference might prove successful.

---

PERIARTERITIS NODOSA.

THE obscure and rare condition known as *periarteritis nodosa* forms the subject of an interesting communication by Dr. Warfield T. Longcope to the February number of the *Proceedings of the Pathological Society of Philadelphia.* The patient whose case was investigated by Dr. Longcope was a coloured man, aged 35 years, admitted to the Pennsylvania Hospital under the care of Dr. James Tyson complaining of præcordial pain, dyspnœa, and œdema of the abdomen and lower extremities. His illness commenced about three weeks before admission with pains in the joints and calves of the legs, slight malaise, and weakness. The legs began to swell four days before admission and his dyspnœa increased. His temperature was 96° F., respirations 28, and pulse 56, the radial pulse being of small volume and tension, thready, and at times irregular. There was tenderness over the liver, which extended 3·5 centimetres below the costal margin. The leucocytes were found to number 13,200 per cubic millimetre. The urine contained a trace of albumin and numerous hyaline and finely and coarsely granular casts. About a fortnight later, after a temporary improvement, the urine suddenly became blood-stained and contained many granular and hyaline casts Later the leucocyte count rose to 32,000, while the hæmoglobin was found to be 58 per cent. The patient became more dyspnœic and died about a month after admission. At the necropsy the heart was found to be enlarged and there was a marked white thickening over its vessels. Near the apex there were greyish and yellowish streaks in the muscle The liver was enlarged and on section presented a curious coarse mottled appearance. Some of the small arteries were found to be plugged with firm red thrombi. Both kidneys showed on section a mottled appearance and it was often difficult to distinguish medulla from cortex. There were numerous small infarctions scattered through the cortex. On following up the renal blood-vessels, thrombi, red or white in character, were found in the arcuate arteries and extended as far as these could be followed. There was extensive softening of the left occipital lobe of the brain, and the left posterior cerebral artery was plugged throughout the greater part of its length by a firm red and grey thrombus. On microscopical examination changes typical of periarteritis nodosa were found in the smaller arteries of the heart, liver, kidneys, pancreas, testicles, brain, perineural connective tissues, and voluntary muscles. There were anæmic infarctions of the kidneys, foci of necrosis in the myocardium and liver, typical glomerular nephritis, and degeneration of voluntary muscles. In the larger vessels longitudinal section showed the presence of the nodules, and on approaching a nodule from a healthy portion of vessel, the first change noticed was in the adventitia where there was infiltration with small round cells, a few polymorphonuclear leucocytes and eosinophiles. A short distance from this changes were found in the intima which presented slight fibrous thickening covered with cells of various types. Somewhat nearer the nodule the media showed swelling of the muscle cells with loss of nuclei. Cross sections showed at the periphery of the nodule involvement first of the adventitia, then the intima, and, finally, more or less complete but often irregular destruction of the internal elastic layer and of the media. Some vessels showed general irregular dilatation of the vessel, others showed bulging on one side; occasionally the lumen was found to be partially occluded by proliferation and infiltration of the cells of the intima, but in other sections it was found to be plugged by a thrombus consisting of red blood corpuscles, polymorphonuclear leucocytes, fibrin, and platelets. The thrombi, like the changes in the walls of the vessels, were localised and were often confined to a very limited area. In older lesions the inflammatory changes were less prominent and the vessel wall was converted into a wide circular ring of cellular connective tissue, in the centre of which was an organising thrombus. In some such nodules no trace was to be found of the original smooth muscle of the media; or of the elastic tissue of the internal or external elastic laminæ. In the smaller vessels the lesions presented certain differences: they were usually clustered in definite lesions corresponding to the bifurcation of the arteries. The perivascular lymphatics at a distance from the nodules were distended with polymorphonuclear leucocytes and large phagocytes. The adventitia of the vessels as well as the perivascular connective tissue showed œdema and infiltration with various cells. This exudate was found to increase and some infiltration with fibrin also appeared until it formed a wide zone around the muscular ring of the media. The intima also showed infiltration with polymorphonuclear leucocytes, fibrin, and large pale cells. The fibrinous exudate in the intima sometimes increased to form a granular ring internal to the media which eventually became involved in the inflammatory process, and in the central part of all nodules it was entirely destroyed. Dr. Longcope, at the end of his valuable paper, discusses briefly the histogenesis and etiology of the disease. He points out that owing to its tendency to involve all the coats it is difficult to be certain of the primary lesion. In his own case he was able to find two instances in which the adventitia about minute arteries showed a localised infiltration with small round cells without changes in the media or the intima, and he is inclined to regard these as the beginnings of nodules. He concludes that in his own case the adventitia was the primary seat of attack, but he is not prepared to suggest that this is the rule in all cases. In regard to the etiology, no evidence was forthcoming to connect it with syphilis and no spirochætæ were demonstrated in sections prepared by the Levaditi method. By some mischance the cultures prepared from the liver and spleen were destroyed, so that no bacteriological studies could be carried out. Bombard in a recent case obtained staphylococcus albus in cultures from the liver and spleen, but with this exception the bacteriological investigation of these cases has given negative results. In spite of these failures, however, Dr. Longcope thinks that many of the features are in favour of the view that the disease is due to an acute infection, notably the fever, the leucocytosis, and the type of the inflammatory exudate. Moreover, the glomerular nephritis present in the cases of Hart and Bombard, as well as in his own case, is consistent with this view of causation by some intoxication or unknown infective agent.

EPSOM COLLEGE AND A BEQUEST.

THE will of the late Surgeon-General Richard Chapman Lofthouse, A.M.S., which consisted of a formal will and five documents explaining the testator's wishes, was considered in the High Court of Justice, Chancery Division, on March 17th and 18th. Although the testator declared that his trustees should, if possible, avoid taking any law proceedings in regard to the construction of and the carrying out of the trusts of his will, and that they should be guided in the application of the residue as much by the terms in the will set forth as by written instructions which he intended to deposit therewith, it was found to be necessary for the court to decide various points, and to discriminate between conditions which were essential and those which were directory only and not of the essence of the gift, that is to say, to determine which conditions were not precedent to the gift taking effect. Judgment was reserved on the conclusion of the hearing of the summons, and Mr. Justice Swinfen Eady delivered a written judgment on April 7th. The testator estimated the amount of the residue at £15,000, but the actual amount proved to be about £40,000. The will provides that an annuity of £100 is to be paid to the testator's sister, Mrs. Mary Ann Stirk; that during her lifetime the residue of the income of the trust is to accumulate and be invested; and that after her death the whole estate is to be realised and devoted to charitable purposes. Various carefully thought out projects and alternative schemes were provided for, but it is unnecessary to refer to these in detail since the court has decided that the first object mentioned in the will is the proper one to be carried out. Therefore the vicar and churchwardens of St. Mary's, Low Harrogate, are to receive the gift, the details of which are as follows: That the trustees are "to pay and apply such sum or sums of money after the death of the said Mary Ann Stirk in the erection of a church with entirely free seats, monument-chapel, and if means permit of a school house, in connexion with the Established Church of England, and also a sum of £1000 towards the endowment of such church (according to the written instructions given), provided the remainder required by the Bishop of the diocese for the endowment of the said church be found or contributed by the Ecclesiastical Commissioners or other Church association within a reasonable time." Any surplus up to £3000 that remains after carrying out the scheme mentioned above is to be equally divided between four charities in Harrogate—namely, the Bath Hospital, the Convalescent Hospital, the Home for Incurables, and the Cottage Hospital; and if a further sum of £1000 remains it is to be paid to the pension fund of Epsom College. The important question was raised whether the accumulations of income might now be stopped, notwithstanding that the testator's sister, Mrs. Mary Ann Stirk, is still living. As this lady objects to such a course being followed, on the ground that if she lives beyond 21 years from the testator's death, she, as sole heiress-at-law and next of kin, may become entitled thenceforward during the residue of her life to the income of the estate, no immediate application and division of the residuary estate can be made. Moreover, the amount which the Epsom College Pension Fund may receive is dependent upon the amount of the ultimate surplus, which in turn may depend upon the length of time during which the income of the trust fund is allowed to accumulate. The accumulation is, therefore, to be continued during the life of Mrs. Mary Ann Stirk, or until further order, not to exceed a period of 21 years from the testator's death.

THE LATE SIR DONALD CURRIE AND MEDICAL EDUCATION.

IT is with great regret that we have learned the death of Sir Donald Currie which took place at Sidmouth on April 13th. Sir Donald Currie was a man well known in the shipping world as the head of the Union Castle Line, while he for many years represented West Perthshire in the House of Commons. With his career as merchant and politician the world has been made very familiar by many excellent obituary notices in the press, but we wish here to lay stress on the fact that he was one of those philanthropists who, working unostentatiously, furthered many schemes for the welfare of his fellow creatures. Of late years he had interested himself in the needs of the Universities of Edinburgh and Belfast, and a little more than five years ago lent his support to the movement which has resulted in the incorporation of University College, London, in the reorganised University of London. To carry out this scheme it was necessary to find funds for the erection of a school of final medical studies in connexion with University College Hospital, and for this purpose Sir Donald Currie gave a sum of £80,000. As if this act of generosity was not sufficient, he further added a sum of £20,000 for the erection of a nurses' home and a maternity students' house in connexion with the same institution, and gracefully added a further sum of £2500 as a gift from his daughters to furnish the latter buildings. When we consider the straitened circumstances into which medical education in London has fallen, such generosity deserves from our profession the warmest thanks and approval. Sir Donald Currie, though well aware of the necessity for rich men to give of their wealth towards the maintenance of the hospitals of London and elsewhere, a duty to which he again and again responded, was none the less keenly alive to the necessity for providing support for the medical schools of the metropolis—institutions the maintenance of which is so important to the public at large. Though, as he stated in public, there was some reason to hesitate to provide funds for hospitals, because in his opinion these should receive support from the rates, there could be none when the needs of the medical schools were considered. He looked upon these as technical institutes of the greatest importance to the capital of the Empire, and in the absence of Government subventions he felt it was the duty of those who could give help to do so. As might be expected, holding these views, he was keenly alive to the necessity for supporting movements which had as their object the advancement of medical knowledge; the problems of disease, no less than high finance and politics, were readily grasped by his acute intellect and at once secured his sympathy and practical support. To him the present state of medical education in this country was a matter of serious import, and he hoped that the time would soon come when the medical teachers, like those of any other department of learning, would receive adequate endowment. His munificent gift for the purpose of the advancement of the interests of the University of London was a practical expression of his cherished views. To him it seemed a remarkable state of affairs that whilst on the continent medical studies receive the support of the various Governments, whether monarchical or democratic, and in America almost fabulous endowment at the hands of its enlightened rich, in London, with its unequalled opportunities for the investigation of disease, medical studies were cramped, and the hospital and medical school teachers were exploited in the interests of the public at large by a system which left the support of teachers and schools to the chance patronage of a comparatively few medical students.

CONGENITAL MALARIA.

THE possibility of the transmission of malaria to the fœtus in utero is a subject of discussion. The parasite has been found in the blood of the new-born on several occasions, but sufficient time had elapsed for post-natal infection. Hitte has described malarial parasites in the blood of the umbilical cord in two cases, but in the article on Malaria in Allbutt and Rolleston's "System of Medicine" Professor W. S. Thayer pronounces the evidence unconvincing. At a meeting of the Société Médicale des Hôpitaux of Paris on Feb. 5th M. Dumolard and M. Viallet reported the following case, which seems to put beyond doubt the possibility of congenital infection. A married woman, aged 31 years, was admitted into the civil hospital of Mustapha, Algiers, on August 12th, 1908. She had three healthy children and was in the seventh month of pregnancy. She lived in a malarious region but had always enjoyed good health until four days before admission, when she became feverish. After four hours the attack ended with abundant perspiration. On each of the following days a similar attack occurred. On examination on the 13th she was free from fever but was very anæmic and showed a slight subicteric tint which was due to hæmolysis, for the urine did not contain any bile. The spleen was markedly enlarged. The red blood corpuscles contained numerous non-pigmented hæmatozoa. On the morning of the 14th another attack occurred. 20 centigrammes of hydrochlorate of quinine were given hypodermically every two hours. On the 15th labour came on and a well-formed living male child weighing five pounds was born. It lived only an hour. Blood from the umbilical cord, the heart of the fœtus, and the placenta showed hæmatozoa like those found in the mother's blood. Quinine was not given on this day, and on the morning of the 16th a very grave attack of fever accompanied by stupor occurred. Three injections of 50 centigrammes of quinine were given on this day. On the 17th there was slight improvement and 20 centigrammes of quinine were given every two hours. On the 18th there was manifest improvement and 150 centigrammes of quinine were given and on the 19th the dose was reduced to 100 centigrammes. On the 20th there were no parasites in the blood and no quinine was given. An abscess formed on the abdomen at the site of the hypodermic punctures and was opened on the 30th. On Sept. 3rd there was phlebitis of the left leg with fever, pain, and œdema, but the uterus showed nothing abnormal and the general condition remained good. Recovery followed. M. Dumolard and M. Viallet considered that this case proves the possibility of the transmission of the malarial parasite across the placenta to the fœtus, for there was no uterine hæmorrhage by which the infection could have been conveyed. The question of the frequency of such transmission remains to be determined. As in other infections, the health of the mother, the virulence of the infection, the age of the fœtus, and alterations in the placenta, no doubt are factors. Many cases have been published to show that even in severe malaria the fœtus is not infected, but its health is often impaired. Probably when it escapes the hæmatozoon itself the toxins filter across the placenta. Another question is the relation of malaria to abortion. Malaria must be regarded as a powerful cause of abortion, which is more likely to occur when, as in the present case, the fœtus is infected. But apart from fœtal infection the destruction of the red corpuscles and the fever in the mother may produce abortion. It follows that a pregnant woman suffering from malaria should be given quinine in sufficient doses. No doubt in exceptional cases quinine excites uterine contractions and produces abortion, but it is the only means of saving the mother and the fœtus from an infection likely to produce abortion and then kill the mother. In the case reported above the infection of the fœtus showed that quinine was doubly indicated.

THE SYSTEMATIC DISINFECTION OF SCHOOL FLOORS.

AN interesting series of experiments indicating the value and importance of disinfecting school floors appears in a report made at the instance of the Buckinghamshire Education Committee by its staff science master, Mr. W. E. Marsh, B.Sc. During the six months from Jan. 1st to June 30th, 1907, the official returns showed that 43 schools were closed owing to epidemics in the county for an aggregate of 137½ weeks, involving a loss of 197,700 attendances. Although these results do not affect the Board of Education grant, as provision is made to allow for such cases, they mean a serious educational loss to the scholars and a waste of time to the teachers. In addition, of course, there is often some loss of life. Thus in a recent epidemic of diphtheria six deaths occurred amongst children in one village, four of whom were attending one school, and in another case no less than 16 children died from the same disease. As Mr. Marsh points out, it is difficult to trace accurately the effect of an epidemic in those cases where it is not severe enough to cause the closure of the school, but there is generally a very considerable drop in the attendances before it is decided to close the school for an epidemic, and in this case there is actual loss of grant to the school. In an instance quoted the grant lost has been estimated to be £80 over a period of six weeks before closing and six weeks following the reopening. In the same way the attendances take some time to regain their normal condition. In Mr. Marsh's preliminary experiments two rooms of similar size, shape, and having about the same number of scholars in each were selected. In one case the floor was sprinkled with plain water (1 gallon to each 400 square feet) and in the other with cyllin solution (1 in 350) in the same proportion. The rooms were left for half an hour and were then swept. Samples of the dust were collected and bacteriologically examined, with the result that an average reduction of from 75 to 85 per cent. of organisms was shown in the dust treated with disinfectant. It was also proved that the organisms in the air were considerably reduced by the disinfection of the floor. Later the Buckinghamshire Education Committee authorised the extension of the experiments, the results of which have been presented by Mr. Marsh in two reports. They show that the spraying was commenced in the first week of February, 1908, and was continued for 12 months. The floors of 24 schools were thoroughly sprinkled each day immediately after dismissal of the children in the afternoon. Each of these schools was paired with a school of the same type in the same district (sometimes in the same town or village) and, as far as could be arranged, with about the same number of children in attendance, so as to be reasonably certain that any abnormal cause of variation in attendance, such as inclement weather, should as far as possible affect both disinfected and non-disinfected schools equally. The result showed for the whole year an increased attendance of 0·76 per cent. at the disinfected schools. This may seem small, but, as Mr. Marsh observes, the difficulty of raising the attendance of course increases rapidly as the percentage approaches the maximum. The foregoing result, he adds, is equivalent to an increase of grant in the county of Bucks of about £500 per annum. The experiments in conclusion appear to Mr. Marsh to teach that the following advantages may be gained by the aseptic treatment of the school floor: (1) the better health of the scholars and teachers; (2) the probability that attacks of infectious diseases would be reduced in number and virulence; (3) the educational gain due to the greater continuity of the instruction following the more regular attendance of the scholars; and (4) the reduction in the cost of elementary education to the ratepayers owing to the increased grant being in excess of the cost of the process of disinfection.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE series of museum demonstrations at the Royal College of Surgeons of England will be brought to a close for the present session by the series which commences on April 23rd, when Professor A. Keith will show and explain the collection of specimens which illustrate malformations of the face, nose, mouth, pharynx, and neck. The demonstrations are given in the theatre of the College, Lincoln's Inn-fields, at 5 o'clock, the first on April 23rd, the second on April 30th, and the last on May 7th. Mr. R. J. Godlee has added to the College collection his series of specimens illustrating the peculiar formation on the palate described as the torus palatinus.

THE annual discussion of the Hunterian Society will be on Diseases of the Thyroid Gland with special reference to Exophthalmic Goitre. It will be opened on Wednesday, April 21st, at 8.30 P.M., by Professor G. R. Murray of Manchester. The discussion will be resumed on Wednesday, April 28th, when Sir Victor Horsley and Mr. James Berry will deal with the surgical aspects of the question. All members of the medical profession are invited to attend.

WE regret to announce the death, at 10, Stratford-place, after a long illness, of Louisa, wife of Sir T. Lauder Brunton. Sir T. Lauder Brunton's many friends will sympathise with him deeply upon his loss. A memorial service will be held at St. Peter's, Vere-street, W., on Saturday at 10.30 A.M., conducted by the Very Rev. the Dean of Salisbury.

A TELEGRAM from the Governor of Hong-Kong to the Secretary of State for the Colonies states that 6 cases of plague were reported during the week ending April 3rd, the number of deaths being five.

THE ROYAL COMMISSION ON THE POOR-LAWS AND RELIEF OF DISTRESS.

VII.[1]

IN CONCLUSION.

IF the reports issued by the Majority and the Minority of the members of the Royal Commission on the Poor-laws lead to no immediate legislative results upon a large scale they have beyond doubt achieved a great work by rousing public feeling. The evils are mostly of very old standing and have been greatly produced or aggravated by popular ignorance or neglect of everything connected with the physiology of education, with the preservation of health, and with the prevention of disease. There is now some prospect that these matters will receive attention and that the extent to which certain strata of our fellow countrymen have become demoralised by dirt and disease will before long be regarded as a national evil for which effective remedies must be sought. Such remedies will be found, we think, mainly in two directions: in a public health service of constantly increasing efficiency, appealing to all sections of the public by precepts, by examples, and by results; and in a gradual tightening up of the law as rapidly as growing public opinion will permit, so as to enable the cases of all gross offenders against sanitary requirements to be dealt with effectively. Parents who leave their children without proper food or clothing are now punishable in our courts, and those who neglect to keep them in a proper state of cleanliness should be punished in a similar manner. The law cannot profitably outstrip public knowledge and public opinion, but it may profitably keep just a step in advance of both and thus lead to their gradual improvement. Nothing useful was ever born full-grown, and no attempt at revolutionising the operations of the Poor-law by a stroke of the pen, or by a single Act of Parliament, is likely to be successful. The reports have, however, served the good purpose of directing attention to many evils for which remedies are required and will probably lead to legislation under which a course of gradual reform may be commenced without delay, and may ultimately be carried to its legitimate termination. We are unable to accept either of these reports in its entirety, but we welcome the light which they throw upon the actual state and conditions of problems which statesmen should feel it an imperative duty to solve. Perhaps the chief thing now to be feared is lest the conflicting advice of discordant counsellors should be employed as an excuse for complete inaction.

To carry one of the reports into effect or to frame legislation based upon selected portions of them, which woul cover the whole ground with which they are concerned, would, indeed, form a task before which the most courageous Cabinet, occupied with other questions of foreign and domestic policy, might pause and ponder. Some da perhaps a set of statutes, in themselves a volume of no mea dimensions, together with their supplementary rules frame by departments and having the force of law, may form monument to the industry of the Commissioners and preserv as the law of the land selected and approved excerpts fro their recommendations. A single Act will, almost obviously not suffice to contain the abolition of the boards of guardians condemned by both reports, and the appointment of their sub stitutes together with, for examples, whatever courses may b prescribed for the diminution of casual labour, and th relief of temporary distress in the cycles of unemployment, o which the reports take cognisance.

The reports of the two sets of Commissioners, as we hav shown in these articles, have common features, as well points of difference; each has been framed in the public servic and with a view to that service by honourable and able me and women, and it is probable that such legislation as ma take place will, as we have suggested, be of a select character. One point at which the two reports are at mark variance is the question of what controlling authority is direct in the future "Public Assistance," the relief, aid, a guidance of the poor, whom we shall have with us alwa however they may be classified, and in spite of su success as we may meet in our efforts to check the augmen tion of their ranks. It may be possible to establish Public Assistance authority upon lines suggested by majority and yet not to adopt the Majority's recommen tions as to the manner in which under that authority medi assistance, for example, is to be supplied to the poor. O may be thought advisable to give weight to the "Pub Assistance" proposals of the Majority and yet to aim at abolition of casual labour and unemployment upon lines s gested by the Minority in an extremely convincing mann The question how the task is to be performed of sift out the more desirable elements in the two reports, and combining them in a homogeneous whole, or in a series homogeneous wholes, is one as to which it is difficult to suggestions. No one can forecast the reply which time bring and which must to some extent depend upon politi developments wholly disconnected from the Poor-law those who administer it. The Minister who at some futu date grapples with the task set him by the Commission have to be one of exceptional attainments, and if he carr it out with any degree of success will enhance his reputati thereby.

Whatever delay may occur, however, and whoever statesman or statesmen may be who will take the fi steps towards initiating a new order of things, direction in which the first movement will be made see fairly clear. Due weight will no doubt be given to memorandum in which Dr. Downes expresses his dou as to the expediency of disturbing existing conditio and care will be exercised lest the change shou produce an interval of confusion and disorganisation, b it seems inevitable that the area of the administration Poor-law relief (to be administered under some new nam will be greatly increased and that the elective council orde ing the local affairs of the area, whatever it may be, w supply in some shape or form the governing authority. T Majority recommend that this should take the form of a ne body, chosen upon lines of a novel character, not consiste with modern tendencies towards representation and publ election, but having advantages which can readily be appr ciated, of independence, continuity, and expert knowledg The Minority would utilise existing committees of council dividing among them the tasks to be performed. Of the two courses, which are not incapable of being combined some extent, that recommended by the Minority has favour of its chances of ultimate adoption the natural desi not to increase the number of local bodies, and the fact th the distribution of the duties of Public Assistance among th various committees named by the Minority may spread the over a wider surface. The truth of the matter is that th effective carrying out of the suggestions of either report far as they affect the local and voluntary administration the law contemplated will impose very considerable task upon those who may be willing to undertake them. The publi spirited men and women who are willing to busy themselve without remuneration, and at some expense to themselves, in the various branches of local government already have their energies pretty severely taxed. It is an open question how much more we can, to use a sporting phrase, "get out of them," and the essential aim of bot[illegible] to be done which will require an [illegible] of trouble, intelligence, and expe[illegible] is now brought into play by the whole combined body of guardians and charitable workers. It is true that we find recommendations which promise paid assistance of various kinds, including increased supervision and direction to be exercised by Government departments, but the fact remains the same, that the men and women will have to be found who will voluntarily carry out arduous duties and will work intelligently and lovingly for results the attainment of which will depend not upon the law under which they are appointed but upon their own goodwill, wisdom, and industry. In a great cause all may wish to be industrious, and if voluntary workers are to be so, surely paid ones may justly be expected not to be laggards. At the same time the Commissioners assume that there is at the command of counties and boroughs an amount of labour [illegible] of time is of no light [illegible] fifth article[2] as to the [illegible] upon the patients who [illegible] rules propounded to them by medical officers. These are to impart advice upon such topics as well as, or in preference to, the prescription of medicine and medical extras, which, regrettably no doubt, are now as a rule the limit of the Poor-law medical officer's assistance to his patient. With the question of the exercise of compulsion the medical profession will not be directly concerned. If it is to be applicable in any form it will be preceded in all cases by instruction and persuasion, having for their object prevention rather than cure. If, however, the medical officer is to pers[illegible] and [illegible] thei[illegible] the [illegible] be e[illegible] results in a statistical form.

---

[1] Nos I., II., III., IV., V., and VI [illegible] THE LANCET of Feb. 27th (p 638), March 6th ([illegible]). 859), and 27th (p 935), and April 10th (p. 106 [illegible]

It is not the desirable character of the objects aimed at by the Commissioners in their recommendations which has been questioned and which will have to be closely considered by the legislator in future sessions of Parliament, but the practical possibility of realising some of their ideals in the ordinary circumstances of life among the working or unemployable poor. The question of compulsion has to be borne in mind continually in perusing both reports, and is not peculiar to either. It arises, for example, when we study the Minority's opinion as to the causes of, and remedy [illegible] the *Times*[3] has asked, "Is it politically possible to take away a man's freedom, or to allow him to starve, not because he will not work at all, but because he prefers not to work continuously?" Of course, when we contemplate the carrying out of the advice of such a body as the Royal Commissioners, whose [illegible] has to be considered. [illegible] may be the first great [illegible] Poor-law is reformed, and may be the one with which the general public will most concern itself. Upon the enlargement of area and upon the institution of a new authority or authorities there will, however, follow necessarily other changes of detail in a large proportion of which the medical profession is concerned, for the greater part of the questions to be settled will be found to involve the physical care of the subject of poor relief with a view to his benefit in the present and to the safeguarding of the public in the future. It will then, no doubt, be found necessary to learn the deliberately formed opinions of persons outside the Commission, applying their personal experience and knowledge not to abstract propositions but to the criticism of formulated regulations affecting their own profession. Dr. Downes uttered a warning upon this subject in his memorandum, to which reference has been made.[4] As an instance of [illegible] already evoked by the report may be cited [illegible] resolutions in which the Poor-law Medical [illegible]ciation has condemned some of the proposals outlined by the majority of the Commissioners as to the medical service to be rendered under the contemplated system of public assistance. These resolutions[5] expressed in uncompromising terms the disapproval of the association with regard to points upon which they may be at variance with the opinion of many lay administrators of the Poor-law and of members of the medical profession who have given evidence before the Commission, but they indicate very plainly that the questions raised are not settled by the Commission's report and that much remains to be said by persons who are clearly entitled to be listened to. It is interesting to note the following passage in the resolutions referred to as supporting the suggestion made above with reference to the magnitude of the scheme of medical work devised by the Commissioners: Resolution (4) "That the Council strongly condemns the proposal to make every medical practitioner a Poor-law medical officer, and it does so for the following reasons." We quote the second reason out of four: "(b) That the value of the work done could never be properly tested, as no system of Local Government Board inspection could deal with so widely extended an arrangement for Poor-law medical relief." Another of the five resolutions passed expresses the Association's disapproval of any change which would allow a poor person to claim State medical relief without the intervention of a relieving officer or assistance officer, a matter concerning the practical organisation of medical assistance upon which the expert opinion of those engaged in such medical work must command attention when any scheme is in a form to which definite criticism can be applied.

As to the matter of possible voluntary assistance, outside that rendered by members of local governing bodies to which reference has been made, more expert evidence will no doubt also be forthcoming, when sections and rules are formulated which for their efficient carrying out require a staff of voluntary workers to perform duties not before existing. [illegible] the Bishop [illegible] comed the [illegible]g with the [illegible] If, how[illegible] detail may [illegible] to observe in conclusion that the reports of the Commissioners, both that of the Majority and that of the Minority, have aroused interest to a very striking degree, and it may be added that the problems of unemployment are so continually before us that this interest is not likely to be permitted to die out. The reports, however, of the Commissioners and that of Dr. McVail[6] draw attention to the urgency of other great questions, and point to possible improvements in existing conditions among the poor which are not so difficult of attainment as the abolition of unemployment. In Dr. McVail's report there is very interesting information with regard to the inadequacy of any effective treatment of phthisis, either curative or preventive, in existing conditions. This is one of many aspects of Poor-law medical relief, the contemplation of which has brought the Commissioners to unanimity in concluding that the existing Poor-law areas and the existing Poor-law authorities are inadequate for the purpose of efficiency and must be changed. The desirability of treating phthisis suitably, of bringing [illegible] out parents, is another subject as to which the pressure of public feeling may not allow the postponement of reform.

The evidence given before the Commission will keep these matters alive, although it is not likely that our fellow citizens generally will assimilate the whole mass of it. The two volumes which have been summarised briefly in these articles, the reports of the Commission and of the Minority, the memorandum of Dr. Downes, and the report of Dr. McVail will be sufficient to content the great majority, and we commend the earnest study of them both to those who desire to appreciate the merits of future legislative proposals and to those who, until the Poor-law is altered, are charged with the administration of it. The latter may effect many improvements in the lot of those intrusted to their care without waiting for the law to compel reform and without exceeding powers which allow considerable scope to their discretion, energy, and intelligence.

[illegible] by Dr. Downes, The Report of the Royal [illegible]

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1907.

THE publication of the annual report of the Sanitary Commissioner with the Government of India is always awaited with interest, for the information which it contains respecting the health of the population of our great Indian Empire, but it is unfortunate that the collection and preparation of statistics relating to this great public health department cannot be issued within a closer period to the year to which it relates. Much of the valuable medical material which the report supplies respecting the health of our troops, British and native, has, moreover, already been published in the searching and thorough report of the Director-General almost a year ago, and we are at a loss to understand the need for the duplication of effort and information.

For some years past the Sanitary Commissioner has compiled an interesting summary of current literature regarding enteric fever, gathered from papers and periodicals published on the Continent of Europe and in America. Much of this literature is written in foreign languages, a good deal of it being in German, which to many practitioners is unfortunately a sealed book. So that this summary with the comments of the Sanitary Commissioner may be said to place at the disposal of its readers the experiments and observations of scientific workers on this subject throughout the civilised world, material which otherwise would not be accessible to a considerable number. These summaries, it may be added, have been admittedly much appreciated, not only by officers of the Indian Medical Service, but by those engaged in public health work at home. Owing to the absence on leave in Europe of Lieutenant-Colonel J. T. W. Leslie, I.M.S., the Sanitary Commissioner, the preparation of the annual report for 1907 was intrusted to the officiating Commissioner, Lieutenant-Colonel C. J. Bamber, I.M.S. The plan of the report is the same as that of previous years and comprises nine sections which deal with different subjects, including the meteorology of the year, the health of the British and native troops, jails, vital statistics of the general population, the history of the chief diseases, vaccination, sanitary works, and general remarks. We are at the present moment dealing in a detailed manner with many of these reports separately. Seven sections of statistical matter are appended in the form of tables which are exceedingly useful for reference purposes.

The Health of the European Army.

Excluding officers, the average daily strength of the European army in India during 1907 was 69,332. Among the body of troops the general health was good, the rates of admission to hospital, of constantly sick, of mortality, and of invaliding being all lower than in the previous year and lower than the rates in the antecedent quinquennium. The first three of the rates above mentioned were the lowest as yet recorded among the European army in India. The decrease of sickness was due chiefly to there being fewer admissions on account of venereal diseases, ague, and simple continued fever (the chief causes of sickness during the

); but nearly

than du

death-rate for 1907 from

to hospital rate,

25·50.

were less

The main causes of invaliding were ague, debility, tubercle of the lungs, valvular disease of the heart, enteric fever, disordered action of the heart, and syphilis, these accounting together for one-half of the total number of invalidings. The number of men sent home on account of ague was 266, compared with 135 in 1906; tubercle of the lungs, 107, as against 92 in the previous year; 76 men were invalided for syphilis and 86 for enteric fever, compared with 120 and 115 respectively in 1906. There were 30 cases of small-pox and one death; 16 of the patients, it appears, had never been successfully revaccinated. The period which had elapsed between revaccination, if any, and the occurrence of the small-pox attack in the 14 other cases is not, however, stated. The patient who died had been vaccinated in infancy but had not been revaccinated. For intermittent fever 10,538 cases were admitted to hospital and nine died. At the divisional laboratories 6633 films of blood were examined for malarial parasites with a positive result in 2415 instances, or 36·4 per cent. Among European troops in India the benign tertian parasite, it seems, is by far the commonest. Only five patients came under observation with Malta fever, compared with seven in 1906. With regard to enteric fever, 910 cases were reported during the year, 192 of them proving fatal, as against 106 attacks and 224 deaths in 1906; the amount of this disease has shown a marked decline during the last five years. The admission rate for enteric fever, 13·1 per 1000 of the average strength, was the lowest recorded since 1388, and similarly the death-rate from it was the lowest since 1885. Enteric fever was more prevalent among the troops in the southern than in the northern army, the divisions showing the greatest incidence being Mhow, Secunderabad, Meerut, and Rawalpindi. Burma showed the smallest incidence. In only one outbreak was the infection traced to contaminated water. Milk was probably the cause of certain cases. Uncooked vegetables and salads purchased from native hawkers were regarded as responsible for some occurrences, and in one instance mineral waters. Flies were regarded as one of the chief agents in spreading the disease at several stations and in some others infected dust was blamed. Two nursing orderlies were found to be bacillus carriers, as also a cook. In the valuable summary of the year's literature of enteric fever, which is given by the officiating Sanitary Commissioner, special attention is directed to the characters of the bacilli of paratyphoid and enteric fevers, the bacteriological methods of diagnosis, the ophthalmic reaction test, the Widal test, the isolation of the bacillus typhosus from the blood, the fæces, and the urine, as also from the tonsils and pharynx. The epidemiology of the disease is also discussed; and the subject of "chronic bacillus carriers," the methods of infection by contact, by water, and by milk, are also considered, as also are preventive measures. References to recent papers dealing with antityphoid inoculation and with serum-therapy are given, along with a list of books and papers referred to in this section. As regards venereal diseases the fall in the rates relating to these is one of the most remarkable features of the statistics of the European army in India, and is attributed in part to the efforts made by the officers and others to occupy the spare time of the men in healthy pastimes, and to make the regimental institutes comfortable and attractive, and by this means influencing the men to avoid contracting venereal infection. There are, too, better education and a higher moral tone among the soldiers, and increased knowledge of the dangers arising from these diseases, causing greater care in personal prophylaxis, and there is also undoubtedly less indulgence in alcohol. There were 17 suicides, of which eight were by gunshot, two by cut throat, two by hanging, one by drowning, one by fracture of the skull, and one each by poisoning with oxalic acid, opium, and sulphuric acid.

The Health of the Native Army of India.

The average strength of the native army in 1907 was 126,392, and their health was generally good, the rate for constantly sick, the invaliding rate, and the death-rate from all causes being the lowest on record. The decreased rate of admission to hospital was [illegible] agne. The [illegible] The truth [illegible] due to the lesser prevalence of [illegible] carrying out of [illegible] far as they affect admission rates for simple continued fever, the law [illegible] venereal diseases were [illegible] dysentery, cholera, diarrhœa, and There was a reduction in the mortality lower than in 1906. remittent fever, but from tubercle of the lungs and there was an increase in the mortality from enteric

fever and ague. The chief causes of sickness were intermittent fever, dysentery, simple continued fever, "other respiratory diseases," venereal diseases, and anæmia and debility. 12 cases were diagnosed as kala azar during 1907, compared with ten in 1906; the diagnosis was confirmed in every instance by finding the Leishman-Donovan parasites in the blood obtained by splenic or hepatic puncture, and in one case in smears from the spleen made after death. The infection, it is believed, was contracted in most, if not in all, cases when the men were on furlough at their homes. Relapsing fever caused 31 admissions and five deaths. There were 182 attacks from enteric fever, 62 from Malta fever, 85 from plague, 48 from small-pox, 34 from cholera, and 24 from typhus fever. The admissions for intermittent fever numbered 27,865, those from remittent fever 567, and from simple continued fever 2094. Tubercle of the lungs caused 324 admissions, and of these 42 died. There were only 1864 admissions for venereal diseases and two deaths. The admission rate for syphilis was 4·9 per 1000, for soft chancre 4·0, and for gonorrhœa 5·8 Guinea-worm caused 472 admissions and beri-beri only seven. Nine cases of suicide among native soldiers were reported in 1907, seven of them by gunshot, one by opium, and one by drowning.

The death-rate from all causes among the native troops was only 6·27, as compared with 8·18 among the European army in India.

The Jails of India.

There is a distinct improvement observed in the health of prisoners detained in the jails of India, the conditions under which they live being more favourable to them than if they lived outside. The scourges of the general population, like cholera and plague, now scarcely affect the prison statistics, and the medical officers of the jails have attained a high degree of success in preventing the spread of other communicable diseases in these institutions. On the other hand, the prison population contains a large number of famine-stricken, weakly, and unhealthy persons, but notwithstanding this the health of the prisoners during 1907 was good and the death-rate, calculated on an average daily population of 107,675 (including the Andaman Islands), was only 18·51 per 1000, the lowest rate as yet recorded in Indian jails. The diseases which caused the most admissions to hospital were intermittent fever, dysentery, abscesses, ulcers, boils, and diarrhœa. The most common causes of death were dysentery, tubercle of the lungs, and pneumonia. 56 cases of epidemic dropsy with five deaths, as also 107 cases of beri-beri, were reported during the year, and special investigations into these two diseases were made respectively by Captain D. Munro, I.M.S., Deputy Sanitary Commissioner of Bengal, and by Captain E. D W. Greig, I.M.S., officiating director of the Central Research Institute, Kasauli.

Vital Statistics of the General Population.

The total population now under registration in India is 225,921,260, but there are still areas which have not yet been brought under registration, including some in the Madras Presidency, the Laccadive and Amindivi Islands, Eastern Bengal and Assam, the North-West Frontier Province, Lower Burma, and also considerable areas in Upper Burma. The population figures on which the rates are calculated are those of the 1901 census; but these obviously become less accurate for purposes of calculation as the date of the census recedes. The total birth [illegible] a birth-rate of 37·65 per [illegible] with 37·80 and 39·13 i[illegible] Central Provinces again showed the highest birth-rate—namely, 52·46, the lowest, 30·8, being yielded by the Madras Presidency. The mean number of males born to every 100 females was 106·8. The total deaths registered amounted to 8,399,623, a death-rate of 37·18, against 34·74 and 35·96 in 1906 and 1905 respectively. The highest death-rate occurred in the Punjab, 62·10, nearly half of which was due to plague. The Presidency of Madras had the lowest death-rate, namely, 24·3. The infantile mortality rate per 1000 children born was 215.

History of the Chief Diseases in India.

More than three-fourths of the total mortality was due to the following causes: "Fevers," plague, cholera, diarrhœa and dysentery, and small-pox, these diseases accounting for no fewer than 6,425,385 deaths out of the total 8,399,623 registered during 1907.

Fevers.—Under this heading, which is a somewhat indefinite one, 4,464,881 deaths were certified, giving a death-rate of 19·76 per 1000 of the population, and accounting for rather more than half of the total deaths from all causes. Many deaths are returned as from "fever" which are due to other causes; it is estimated that rather more than a million of them were due to malaria, and as plague was widely prevalent probably a number of deaths from it were returned as "fever." The provinces which yielded the largest number of deaths from "fevers" were the United Provinces and Bengal, which had respectively 1,350,405 and 1,171,540 such deaths reported.

Plague.—The deaths from plague in 1907 numbered 1,315,707 the highest total as yet recorded in any year since the beginning of the present epidemic in India. In the previous year only 300,355 plague deaths had been registered. The province which suffered most from plague in 1907 was the Punjab, where 608,685 fatal cases occurred, nearly a half of the total plague deaths in India during the year. In the United Provinces there were 328,862 fatal plague cases, in Bombay Presidency 93,609, and in Bengal 83,602.

Cholera.—[illegible] The total [illegible] (including t[illegible] in 1906. The provinces in which the greatest number of cholera deaths occurred were Bengal, where 205,702 were certified; the Madras Presidency, 81,565; Eastern Bengal and Assam, 77,181; and the United Provinces, 22,438.

Diarrhœa and dysentery.—Under this heading 298,117 deaths were reported during the year, of which the Madras Presidency had 60,326; Bombay Presidency, 53,708; and Bengal, 51,670.

Small-pox.—From this cause 103,988 deaths were certified in 1907, as against 109,583 in 1906, and 70,912 in 1905 Of the deaths in 1907 Bengal was responsible for 29,066, the United Provinces for 22,645, and the Madras Presidency for 22,455.

Vaccination.

The total vaccinations amounted in the year to 9,169,873, which is a slight increase over the number performed in 1906. The percentage of success attained in primary cases was 97·65 and in revaccinations 75·45. All the provinces, except the Central Provinces and the North-West Frontier Province, as well as the two small provinces of Ajmer-Merwara and Coorg, maintain their own vaccine institutes for the production of lymph.

General Remarks.

At the Central Research Institute, Kasauli, as regards original research, the staff was engaged mainly in carrying on the inquiry regarding the etiology and mode of spread of enteric fever in India, which was begun in 1906. Other investigations connected with the problems of immunity and vaccine therapy were in progress at the end of the year. Investigation of the etiology and mode of spread of dysentery, on the same lines as that of enteric fever, has been begun. This institute also was engaged in the preparation of antivenene and curative sera, and also in routine bacteriological examination of specimens sent for diagnostic purposes. The Bombay Bacteriological Laboratory is used (1) for the preparation and issue of antiplague vaccine for the whole of India; (2) as the chief laboratory for plague research work; and (3) as the provincial laboratory for the Bombay Presidency. At the King Institute of Preventive Medicine, Madras, the bacteriological examination of specimens from medical officers, sanitary authorities, plague officials, and others, is carried out; also the chemical and bacterioscopic examination of water; and other scientific work is undertaken At the Pasteur Institute, Kasauli, 1349 persons, of whom 433 were Europeans, underwent the antirabic treatment in 1907 for bites of animals, mostly dogs; but in addition to 123 cases bitten by jackals there were others bitten by wolves and cats. There were only six failures to secure immunisation. This institute also serves as the provincial laboratory for the Punjab. The Pasteur Institute of Southern India, Coonoor, was opened in April, 1907; in it 186 patients have been treated, of whom four did not complete the full course. One patient died on the seventh day and eight remained under treatment at the end of the year. There was no failure, since the fatal case had been bitten by a jackal 29 days before he came under treatment.

It is satisfactory to learn that the Secretary of State towards the end of 1907 sanctioned proposals for placing the various existing appointments connected with the bacteriological laboratories on a definite footing and for the creation of additional appointments. A list of scientific publications issued during the year by members of the Indian Medical Service is appended.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 16th, 1831.

INVENTION OF THE STOMACH-PUMP.

To the Editor of THE LANCET.

SIR,—While turning over, the other day, the lectures of Sir A. Cooper, published by you in THE LANCET, I was surprised to find Sir Astley attribute the invention of the stomach-pump, as applicable to the removal of poisons from the stomach, to Mr. Jukes of Pimlico, in the following words:—"With respect to the medical application of the syringe, however, for the purpose of removing poisons from the stomach, we are indebted for it to Mr. Jukes." Without wishing to detract from the merit of Mr. Jukes, in having introduced to public notice so valuable an instrument, I must remark that a precisely similar instrument was invented, many years since, by M. Renault, a French surgeon and that a description of it by Alibert exists as far back as the year 1804. An extract may not be uninteresting to those who dip a little into medical literature.

"If great difficulty be experienced in compelling the stomach of a person who has taken poison, to reject its contents, if the jaws be affected by tetanus to such a degree that nothing can be introduced into the stomach, M. Renault proposes that we have recourse to a tube of gum-elastic, of sufficient length to reach by one extremity into the stomach, and of sufficient calibre to give free passage to any matter we may wish to introduce into this viscus. The external extremity of the tube is mounted with a metal ring, to which a syringe may be adapted. M. Renault is of opinion that, with the assistance of this tube, we may inject a sufficient quantity of liquid into the stomach and afterwards withdraw it by the action of the piston."

I remain, Mr. Editor,
Your obedient servant,
P. H. GOWER.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8802 births and 5653 deaths were registered during the week ending April 3rd. The annual rate of mortality in these towns, which had been 22·1 and 19·8 per 1000 in the two preceding weeks, further declined to 17·9 in the week under notice. During the 13 weeks of the past quarter the death-rate in these towns averaged 18·8 per 1000, and in London the mean rate during the same period was equal to 19·6 per 1000. The lowest annual death-rates recorded in these towns in the week under notice were 6·0 in Hornsey, 8·0 in Walthamstow, 8·3 in Barrow-in-Furness, and 8·9 in Smethwick; the rates in the other towns ranged upwards to 24·4 in Oldham, 27·0 in Wigan, 27·3 in Great Yarmouth, 28·1 in Warrington, and 30·7 in St. Helens. In London the recorded death-rate during the week was equal to 18·3 per 1000. The 5653 deaths from all causes in the 76 towns during the week showed a further decline of 598 from the number in the preceding week, and included 578 which were referred to the principal epidemic diseases, against 725 and 683 in the two preceding weeks; of these 578 deaths, 329 resulted from measles, 103 from whooping-cough, 49 from diphtheria, 46 from diarrhœa, 41 from scarlet fever, nine from "fever" (principally enteric), and one from small-pox. No death from any of these epidemic diseases was registered during the week in Gateshead, Leyton, Birkenhead, Halifax, or in nine other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 4·0 in Preston, 8·6 in Wigan, 9·4 in Warrington, and 15·9 in St. Helens. The fatal cases of measles, which had been 438 and 410 in the two preceding weeks, further declined to 329 in the week under notice; the highest death-rates from this disease were 3·1 in Reading and in Sheffield, 3·8 in Bootle, 3·9 in West Hartlepool, 4·6 in Wigan, 8·7 in Warrington, and 14·8 in St. Helens. The 103 deaths from whooping-cough showed a further decline from the numbers in recent weeks, but caused death-rates equal to 1·1 in St. Helens and in Swansea, 1·7 in Norwich, and 3·1 in Preston. The 49 deaths from diphtheria were ten fewer than the number in the preceding week, the highest death-rate from this disease being 1·1 in Huddersfield. The 46 fatal cases of diarrhœa exceeded the number recorded in any of the previous six weeks; in Wigan the mortality from this cause was equal to 2·9. The 41 deaths from scarlet fever showed no variation from the number in the preceding week, and included 12 in London and its suburban districts, ten in Manchester, and four in Liverpool. The nine deaths referred to "fever" showed a further considerable decline from the numbers in recent weeks. The fatal case of small-pox was recorded in Bristol. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospitals, which had been 2596 and 2571 at the end of the two preceding weeks, had further decreased to 2462 on April 3rd; the new cases of this disease admitted to these hospitals during the week numbered 273, against 279 and 327 in the two preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 651 and 567 in the two preceding weeks, further declined to 399, but were 55 in excess of the corrected average number in the corresponding week of the five years 1904–08. The deaths in London referred directly to influenza during the week declined to 107, but exceeded the corrected average by 75. The causes of 51 or 0·9 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, and in 46 other smaller towns; of the 51 uncertified causes of death, however, nine were registered in Liverpool, eight in Birmingham, four in Sheffield, and three in London and in Manchester.

During the week ending April 10th 8230 births and 5364 deaths were registered in 76 of the largest English towns. The annual rate of mortality in these towns, which had declined from 22·1 to 17·9 per 1000 in the four preceding weeks, further fell to 17·0 last week. For the 13 weeks of the past quarter the death-rate in these towns averaged 18·8 per 1000, and in London the mean rate for the same period was 19·6 per 1000. The lowest recorded death-rates in these towns last week were 4·4 in Hornsey, 7·8 in Stockton-on-Tees, 8·2 in Handsworth (Staffs), and 8·4 in Walthamstow and in Ipswich; while the rates in the other towns ranged upwards to 24·5 in Birkenhead, 28·2 in Middlesbrough, 29·0 in Tynemouth, and 31·8 in St Helens. In London the recorded death-rate during the week was equal to 15·9 per 1000. The 5364 deaths from all causes in the 76 towns last week showed a decline of 284 from the number in the previous week, and included 593 which were referred to the principal epidemic diseases, against 725, 683, and 573 in the three preceding weeks; of these 593 deaths, 327 resulted from measles, 107 from whooping-cough, 53 from diphtheria, 47 from scarlet fever, 37 from diarrhœa, and 22 from "fever" (principally enteric), but not any from small-pox. The 593 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·9 per 1000, against rates declining from 2·3 to 1·8 in the three preceding weeks. No death from any of these epidemic diseases was registered last week in Leyton, Halifax, Hornsey, Newport (Mon.), Ipswich, or in six other smaller towns; the death-rates therefrom ranged upwards, however, to 4·5 in Bootle, 4·6 in Portsmouth, 6·5 in Sunderland, and 10·4 in St. Helens. The fatal cases of measles in the 76 towns, which had declined from 438 to 329 in the three preceding weeks, further fell to 327 last week; the highest death-rates from this disease in the week under notice were 3·0 in Bootle, 3·1 in Reading, 3·2 in Portsmouth, 3·3 in Sheffield, 5·2 in Sunderland, and 8·2 in St. Helens. The 107 deaths from whooping-cough showed a slight increase over the number in the preceding week, and caused death-rates equal to 1·0 in Walsall and in Stockport, 1·1 in St. Helens, 1·2 in York, 1·3 in Coventry, and 1·5 in Rhondda. The 53 fatal cases of diphtheria were four in excess of the number in the previous week, the highest death-rates from this cause being 1·0 in Portsmouth and in Wolverhampton and 1·2 in Rhondda. The 47 deaths from scarlet fever exceeded the number recorded in any of the preceding 11 weeks, and caused rates ranging upwards to 1·3 in King's Norton and 2·2 in Wallasey. The 37 fatal cases of diarrhœa showed a decline from the numbers in recent weeks; the highest death-rates from this disease were 1·1 in Swansea, 1·2 in Aston Manor, and 1·5 in Smethwick. The deaths referred to "fever," which had been 22, 15, and nine in the three preceding weeks, rose again to 22 last week, and included two each in London, Manchester, Huddersfield, and Middlesbrough. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the *London Fever Hospital*, which had declined from 2873 to 2462 at the end of the five preceding weeks, had further fallen to 2418 on Saturday, April 10th; 256 new cases were admitted during the week, against 279, 327, and 273 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had decreased from 758 to 399 in the four [illegible] ek to 310, and were [illegible] the corresponding [illegible] deaths in London referred directly to influenza fell last week to 62, having been 125, 138, and 107 in the three preceding weeks. The causes of 44, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Leeds, Bristol, West Ham, Newcastle-on-Tyne, Nottingham, Salford, and in 48 other smaller towns; the 44 uncertified deaths included seven in Birmingham, five in Gateshead, four in Liverpool and in Sheffield, and three in Manchester and in St. Helens.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·6, 21·1, and 20·5 per 1000 in the th[illegible] further declined to 19·9 in the wee[illegible]g the 13 weeks of the past qu[illegible]ese eight towns averaged 19·5 [illegible] 0·7 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates during the week under notice ranged from 13·8 in Aberdeen and 15·2 in Leith, to 23·3 in Paisley and 24·5 in Greenock. The 712 deaths from all causes registered in the eight towns showed a further decline of 20 from the numbers in recent weeks, and included 78 which were referred to the principal epidemic diseases, against 96, 87, and 80 in the three preceding weeks; of these 78 deaths, 47 resulted from whooping-cough, 14 from diarrhœa, six [illegible] let fever, five from "fever," [illegible] any from small-pox. These [illegible] ses were equal to an annual rate of 2·2 per 1000, or 0·4 per 1000 above the mean rate during the week from the same diseases in the 76 English towns. The fatal cases of whooping-cough, which had been 51 and 52 in the two preceding weeks, declined again to 47 in the week under notice, and included 32 in Glasgow, nine in Aberdeen, three in Edinburgh, and two in Dundee. The [illegible] from scarlet fever also occurred in Glasgow, as did three of the five deaths referred to "fever," of which two were certified as enteric fever and one as cerebro-spinal meningitis; one fatal case of enteric fever occurred in Perth and one of cerebro-spinal meningitis in Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 187 and 180 in the two preceding weeks, further declined to 163 in the week under notice, but exceeded by 49 the number registered in the corresponding week of last year. The causes of 26, or 3·8 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·9 per cent.

The annual rate of mortality in eight of the principal Scotch towns, which had declined from 21·6 to 19·9 per 1000 in the four preceding weeks, further fell to 17·7 per 1000 in the week ending April 10th. During the 13 weeks of the past quarter the annual death-rate in these eight towns averaged 19·5 per 1000, and exceeded by 0·7 per 1000 the rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates in the week under notice ranged from 11·9 in Paisley and 13·4 in Leith, to 19·6 in Glasgow and 20·6 in Dundee. The 634 deaths from all causes registered in the eight towns last week showed a further decline of 78 from the number in the preceding week, and included 90 which were referred to the principal epidemic diseases, against 87, 80, and 78 in the three preceding weeks; of these 90 deaths, 55 resulted from whooping-cough, 13 from diarrhœa, nine from diphtheria, seven from "fever," three from measles, and three from scarlet fever, but not any from small-pox. These 90 deaths were equal to an annual rate of 2·5 per 1000, being 0·6 per 1000 above the mean rate last week from the principal epidemic diseases in the 76 large English towns. The fatal cases of whooping-cough in the Scotch towns, which had been 52 and 47 in the two preceding weeks, rose again last week to 55, of which 42 occurred in Glasgow, four in Dundee, three in Edinburgh, and two in Aberdeen. The 13 deaths from diarrhœa were slightly below the number in the previous week, and included eight in Glasgow and three in Dundee. The fatal cases of diphtheria, which had been 12, eight, and six in the three preceding weeks, rose again last week to nine, of which four were registered in Glasgow and two in Dundee. Of the seven deaths referred to "fever," four of enteric and two of cerebro-spinal meningitis occurred in Glasgow, and one of cerebro-spinal meningitis in Paisley. All the three fatal cases of scarlet fever were registered in Glasgow; and two of the three deaths from measles occurred in Aberdeen. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 187, 180, and 163 in the three preceding weeks, further fell to 108 in the week under notice, and were 20 fewer than the number in the corresponding week of last year. The causes of 25, or 3·9 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 29·3 and 27·2 per 1000 in the two preceding weeks, further declined to 25·9 per 1000 in the week ending April 3rd. During the 13 weeks of the past quarter the death-rate averaged 25·7 per 1000, the mean rate during the same period being 19·6 in London and 18·1 in Edinburgh. The 198 deaths of Dublin residents from all causes during the week under notice showed a further decline of ten from the numbers in the two preceding weeks, and included 20 which were referred to the principal epidemic diseases, against 17, 13, and ten in the three preceding weeks. These 20 deaths were equal to an annual rate of 2·6 per 1000; the rate from these epidemic diseases in the same week was equal to 1·8 in London, and did not exceed 0·9 [illegible] diarrhœa; the mortality from each of these diseases exceeded that recorded in recent weeks. No death from small-pox, from scarlet fever, or from "fever" was registered during the week under notice. The 198 deaths in Dublin during the week included 36 of infants under one year of age and 56 of persons aged upwards of 60 years, the latter being 15 below the [illegible] in each of the two preceding weeks. Thre[illegible] from [illegible] were regis[illegible] or 3[illegible] of the deaths occurred in public institutions. The causes of five, or 2·6 per cent., of the deaths in Dublin last week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all but three of the 1701 registered deaths were duly certified; while in Edinburgh 5·6 per cent. of the causes of death were uncertified.

The annual rate of mortality in Dublin, which had declined from 29·3 to 25·9 per 1000 in the three preceding weeks, further decreased to 25·5 in the week ending April 10th. During the 13 weeks of last quarter the death-rate averaged 25·7 per 1000, whereas the mean rate during the same period did not exceed 19·6 in London and 18·1 in Edinburgh. The 195 deaths of Dublin residents from all causes during the week under notice showed a further slight decline from the numbers in recent weeks, and included 17 which were referred to the principal epidemic diseases, against 10 and 20 in the two preceding weeks. These 17 deaths were equal to an annual rate of 2·2 per 1000; the rate from these epidemic diseases in the same week was equal to 1·8 in London and 0·6 in Edinburgh. Of the 17 deaths from these epidemic diseases in Dublin last week, seven resulted from whooping-cough, six from measles, two from diarrhœa, one from diphtheria, and one from "fever," but not one either from scarlet fever or from small-pox; the deaths from whooping-cough just exceeded the number in the preceding week, while those from measles showed a small decrease. The 195 deaths registered during the week included 39 of infants under one year of age and 52 of persons aged upwards of 60 years; these numbers being respectively three above and six below the corresponding numbers in the previous week. Seven inquest cases and four deaths from violence were registered; and 89, or 45·6 per cent., of the deaths occurred in public institutions. The causes of six, or 3·1 per cent., of the deaths in Dublin last week were not certified either by a registered medical practitioner or by a coroner; in London all of the 1470 deaths were duly certified, while in Edinburgh 3 per cent. of the causes of death were uncertified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets James Porter, C.B., Director-General of the Medical Department of the Navy, has been appointed Honorary Physician to His Majesty, in place of Inspector-General of Hospitals and Fleets Sir John Watt Reid, K.C.B., LL.D., K.H.P., deceased (dated Feb. 25th, 1909).

The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's fleet: Alfred James Hewitt (dated Feb. 26th, 1908), John Verdon (dated August 2nd, 1908), and John Thornhill (dated Feb. 11th, 1909).

The following appointments are notified:—Fleet-Surgeons: H. W. G. Doyne, H. W. Finlayson, H. W. Gordon-Green, and A. S. G. Bell to the *President*, additional, for three months' course at West London Hospital; and J. Chambers to the *President*, additional, for three months' course at West London Hospital. Staff-Surgeons: R. H. Mornement, W. G. Westcott, J. O'Hea, H. V. Wells, D. V. Lowndes, P. F. Alderson, and G. O. M. Dickenson to the *President*, additional, for three months' course at West London Hospital; J. Verdon to the *Kinsha;* M. P. Jones and A. W. B. Livesay to the *President*, additional, for three months' course at West London Hospital; J. Whelan to the *Adventure;* J. Mowat to the *Cressy;* A. J. Wernet to the *Iphigenia;* M. Cameron to the *Attentive* (appointment to the *Cressy* cancelled); W. B. Macleod to the *Bonaventure;* and H. Huskinson to the *Africa.*—Surgeons: M. T. Male to the Royal Marine Artillery, Eastney; P. T. Nicholls to the *Victory*, additional, for disposal; E. Cameron to the *Terrible;* S. F. Dudley to the *Commonwealth;* and G. L. Buckeridge to the *Astræa*. Civil Practitioner: H. D. Johns, to be Surgeon and agent at Hornsea and Aldborough.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Francis A. B. Daly, C.B., retires on retired pay (dated April 14th, 1909).

ROYAL MALTA ARTILLERY.

Surgeon-Captain Alfred E. Mifsud to be Surgeon-Major (dated April 1st, 1909).

SPECIAL RESERVE.

Royal Army Medical Corps.

The rank of Captain James C. McCarroll is as now described, and not as stated in the *Gazette* of Nov. 17th, 1908.

Captain Herbert E. Dalby, having assented to be transferred, is appointed an officer of the Special Reserve of Officers, retaining the rank and seniority which he held in the Militia (dated Sept. 20th, 1908).

MILITIA.

Royal Army Medical Corps.

Lieutenant James C. McCarroll to be Captain (dated August 18th, 1908).

TERRITORIAL FORCE.

Royal Field Artillery.

3rd East Anglian (Howitzer) Brigade: Surgeon-Lieutenant Richard W. Mullock to be Surgeon-Captain (dated April 1st, 1908). 1st Northumbrian Brigade: Surgeon-Major John V. W. Rutherford is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated March 31st, 1908).

Royal Army Medical Corps.

1st London (City of London) General Hospital: Major Howard H. Tooth, C.M.G., is seconded for service with the London University Contingent, Senior Division, Officers Training Corps (dated March 13th, 1909).

1st North Midland Field Ambulance: Charles Damien Lochrane to be Lieutenant (to be Supernumerary) (dated Feb. 4th, 1909).

2nd Northern General Hospital: Surgeon-Captain Reginald George Hann, from the 7th Battalion, The Prince of Wales's Own (West Yorkshire Regiment), to be Major (dated Feb. 22nd, 1909).

For attachment to Units other than Medical Units.—Supernumerary Surgeon-Lieutenant William Dyson from the 4th Battalion, The King's (Shropshire Light Infantry), to be Lieutenant (dated March 10th, 1909). Thomas Heyliger Richmond to be Lieutenant (dated August 2nd, 1909). Captain Edmond U. F. MacW. Bourke to be *Major* (dated March 1st, 1909). Cyril Howard Welch to be Lieutenant (dated March 9th, 1909).

THE CLOSE OF THE SESSION AT HASLAR.

The course of instruction of the newly entered surgeons at Haslar was brought to a close on March 30th by the distribution of prizes by the Commander in Chief at Portsmouth, Admiral Sir A. D. Fanshawe, K.C.B. The gold medal was gained by Surgeon W. A. H. McKerrow of the University of Aberdeen; the microscope was awarded to Surgeon F. G. Hitch of the London Hospital; and the silver medal and books were awarded to Surgeon J. Glaister of the University of Glasgow. The following list shows the places gained by the combined marks of the London and Haslar examinations:—

No.		Marks.	No.		Marks.
1.	Surgeon W. A. H. McKerrow	5479	7.	Surgeon A. V. J. Richardson	4123
2.	Surgeon F. G. Hitch ...	5446	8.	Surgeon F. W. Quirk ...	3993
3.	" J. Glaister ..	4763	9.	" S. L. McBean ...	[illegible]
4.	" T. R. Lloyd-Jones	4586	10.	" G. R. McGowan	3830
5.	Surgeon F. G. H. R. Black	4575	11.	" E. J. H. Garstin	3743
6.	Surgeon C. F. Bainbridge	4457	12.	" W. Mearns ...	3554
			13.	" W. Bradbury ...	3535
			14.	" A. C. Wilson	Absent ill.

Eight of the competitors held University degrees.

WEST LONDON HOSPITAL, HAMMERSMITH.—At the annual meeting of the supporters of this hospital the Duke of Abercorn, the president of the hospital and chairman of the meeting, appealed for annual subscriptions and said that there had been a large falling off in legacies and donations. The Bishop of London expressed his regret that this should be so, adding that this hospital was a kind of life-boat for that part of London and that the amount given by the King's Hospital Fund was a vote of confidence in the hospital. It is particularly desired to improve the accommodation provided for the nurses.

"Audi alteram partem."

TIN IN CANNED FOODS.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a letter in THE LANCET of April 3rd, in which Dr. H. W. Wiley expresses his opinion that the results of certain experiments made by Dr. Schryver on this subject (taking known doses of non-irritant salts of tin with a view to determining the degree to which tin was absorbed from the alimentary tract) had better not have been stated because the statement may give encouragement to canners to continue improper practices.

Criticisms from Dr. Wiley on a matter of this sort deserve very careful consideration. He is chief of the Bureau of Chemical Industry in the United States, his efforts to secure the greater purity of foods are well known and appreciated in this country, while in the case of canned foods he has been endeavouring to secure the use of better grades of tin plate by American canners. Dr. Schryver and I have recently made reports to the Local Government Board—"On the Presence of Tin in Certain Canned Foods"—which include an account of the experiments referred to. The statement to which Dr. Wiley takes exception was—

> They (these experiments) do not indicate much probability of serious risk of chronic poisoning by the absorption of non-irritant compounds of tin as a result of a diet which consists largely of canned foods and is continued over considerable periods of time.

If this is objected to, I can only say that it is not the practice in this country to withhold the results of experiments which have been carefully carried out even for such laudable objects as those indicated in Dr. Wiley's letter. I should not, however, have troubled you with any comment on this matter were it not for the consideration that, coupled with your own note on our reports in THE LANCET of Feb. 6th, Dr. Wiley's letter may convey the impression that the general effect of these reports is to suggest that no attention is required in the interests of public health to contamination of foods by tin.

To avoid any such misconception by your readers who have not seen the reports themselves, I would point out that they cover a considerably wider field than the individual experiments which Dr. Wiley discusses. The latter are contained in a section of Dr. Schryver's report which deals with the evidence available as to the accumulation of tin in the body as a result of continued ingestion of small quantities of tin such as are frequently present in properly canned foods of ordinary age. But Dr. Schryver's report also includes a collection of cases in which canned foods containing unusually large amounts of tin have been associated with definite irritant poisoning, and has further indicated the extent to which the degree of contamination of canned foods by tin is governed by the character of the food canned and the time which has elapsed since canning.

The need for discouraging the use by canners of unsatisfactory tin plate, together with the importance of avoiding contamination by tin through improper methods of soldering, is given prominence in my report, which also contains suggestions as to the control which sanitary authorities in this country may be able to exercise in the matter. It appears to be established that practically all canned foods contain some tin, and that at present no positive evidence can be ascertained of harm resulting from the small quantities of tin which may frequently be taken in this way. No suggestion has been made, however, that precautions should not be taken to prevent the introduction of exceptional or excessive amounts of tin into these foods. The basis of such precautions is the employment of satisfactory tin plate and methods of soldering, and also recognition of the fact that contamination by tin increases with the age of the can—a matter of practical importance where acid foods such as canned fruits and meat extractives are concerned. I cannot, however, admit that because this is the end to be attained we should be justified in suppressing the results of experiments because these results may possibly be misused by unscrupulous people.—I am, Sir, yours faithfully,

London, April 14th, 1909. G. S. BUCHANAN.

SPONTANEOUS CURE OF THORACIC ANEURYSM.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 3rd and 10th accounts have appeared of the spontaneous cure of thoracic aneurysm. The following case bears upon these, not so much as a case of complete spontaneous cure, but one of nature's attempts at the same, where visible changes could be watched with the naked eye. About Michaelmas, 1906, a man, about 46 years of age, complained of pain in the chest and lower ribs. The pain in the chest extended through to the shoulder blades and the muscles of the back of the neck. This latter symptom had, he told me, led to a diagnosis of muscular rheumatism. When I saw him about 12 months later, he then told me that he had left off work just previously and was suffering from rheumatism in his neck. On placing the hand over the front of the chest a distinct heaving impulse was felt, and upon auscultation a double murmur. In due course a very troublesome cough set in with dyspnœa. There was no œdema or loss of voice, nor any hæmoptysis. About six weeks after I first saw him the heaving impulse distinctly pointed at the side of the sternum about the level of the third rib cartilage, and a pulsating swelling of about the size of a hen's egg made its appearance, occupying quite half of the breadth of the sternum. The man was now bad, and it seemed a question whether the aneurysm would burst through the skin or into the bronchus, and as the skin remained intact I fully expected the latter at any moment. I had him watched night and day and kept him absolutely quiet in bed and administered morphia regularly. After some weeks of expectation the man began to improve; the pulsating swelling which probably perforated the sternum without any spontaneous fracture lessened and finally disappeared, and at the present time, with the exception of a little tenderness in the third interspace to the left of the sternum, nothing remains to tell the tale. In the absence of any definite pressure symptoms or any alteration in either pulses or carotids or subclavians I considered the case to be one of aneurysm of the first part of the arch with a considerable sacculus giving the outward and visible signs. The man felt so much better that he wished to resume his ordinary occupation, but to this I would not consent.

In his present condition the patient presents a chest distinctly generally bulged and heaving on the left side, dull on percussion from the left clavicle to the right edge of the sternum. There is a soft systolic murmur all over both sides of the chest. There is a thrill over the left subclavian artery and a systolic murmur over the right subclavian and right carotid arteries. A systolic murmur is heard over the back. The right chest also heaves, but there is no tumour or thrill, and over the left side the breath-sounds are almost inaudible.—I am, Sir, yours faithfully,

JOHN J. WADDELOW, F.R.C.S. Eng.

Whittlesey, April 12th, 1909.

To the Editor of THE LANCET.

SIR,—About 30 years ago a chaplain to the forces who had been under treatment by the late Mr. Tufnell for aortic aneurysm was waiting for his train at the King's Bridge station, Dublin, on his way to the Curragh to resume duty. He suddenly leaped over the wall of the platform on to the foreshore of the Liffey, falling perhaps 20 feet. Although he fractured no bones he died from shock. He had been brought to Dr. Steevens' Hospital, and at the post-mortem examination it was seen that the solid clot which filled the aneurysm was in no way disturbed by the fall, and I very distinctly remember its smooth surface where it filled the entrance from the lumen of the artery.

I am, Sir, yours faithfully,

T. O. D.

April 12th, 1909.

THE CLINICAL VALUE OF HÆMOMANOMETER OBSERVATIONS.

To the Editor of THE LANCET.

SIR,—I regret to find that I have drawn an inaccurate inference from Professor Starling's experiment referred to in my letter in THE LANCET of April 3rd—the result of a hurried glance through his Mercers' Company lectures which had just come into my hands, and of not allowing enough for the difference between mercury and sulphate of magnesia solution. The relations between the arterial and venous pressures were: At the beginning, 11 arterial (Hg) to 14 venous ($MgSO_4$ solution); during experiment, 5 arterial (Hg) to 17·5 venous ($MgSO_4$ solution). The experiment did not show the height to which venous engorgement pressure can be raised, as the venous outflow was not arrested, it was only impeded.

The controversy initiated by Dr. Leonard Hill seems to me to have narrowed itself down to the question of the height to which *venous engorgement* pressure can rise. I have quite "grasped the fact" that Dr. Hill believes "that the venous blood pressure cannot exceed the arterial." I have, however, also grasped the fact that Dr. Hill's observations do not prove what they were thought to prove, but seem to prove, if they prove anything, the unsoundness of the proposition that venous engorgement pressure cannot exceed arterial. I entirely agree with him, however, that it is useless to continue the discussion further, but I would venture to suggest that a point has been defined where experimental physiology might be of assistance in settling the question, which is of somewhat wide interest from its relations to various phenomena which I have avoided referring to in this correspondence.

In closing the correspondence as far as I am concerned, I desire to express my appreciation of Dr. Oliver Williamson's generous recognition of the accuracy of my clinical observations. I am, Sir, yours faithfully,

Edinburgh, April 10th, 1909. WILLIAM RUSSELL.

THE PROXIMATE FACTOR OF DELIRIUM TREMENS.

To the Editor of THE LANCET.

SIR,—I cannot altogether concur with the views expressed by Dr. F. Hare in his letter to THE LANCET of April 10th. I am not in agreement with him in his statement that "delirium tremens is a complication which mainly, if not solely, affects the chronic alcoholic as distinguished from the dipsomaniac and the numerous varieties of impulsive drunkards," &c.

In my experience, and I have referred to the records of several hundreds of cases, there are many more regular or continuous drunkards than periodic drunkards, but the latter are just as liable to suffer from delirium tremens as are the former. And while the cutting off of liquor without the substitution of suitable treatment may precipitate an attack of the malady, the disorder may and does occur among those who are at the time drinking heavily, and who are not troubled with vomiting or other symptoms which denote that the digestive tract refuses to retain or to absorb alcohol. Referring to the Norwood Sanatorium report of which notice has been taken in your issue of March 27th, that institution is described as being under the supervision of an influential advisory medical committee, and it is advertised that the object of the institution is to "place the therapeutics of inebriety upon a definite scientific basis," an advertisement, by the way, which seems to reflect on the labours of such men as Sir B. W. Richardson, Dr. Norman Kerr, and many others. The admission, therefore, that in such an institution there occurred during two years some 6 per cent. to 7 per cent. of such grave complications as delirium tremens and alcoholic epilepsy is a somewhat startling one.

Dr. Hare appears to desire further clinical evidence as to the advisability of a sudden discontinuance of alcoholic liquors in the treatment of inebriates. I will give him clinical evidence. At the Dalrymple Home retreat during the past 25 years there have been admitted some 900 inebriates. During the first 15 years of this period Dr. R. Welsh Branthwaite held the post of medical superintendent, and in this period there occurred three cases of after admission delirium tremens. One occurred a few weeks after Dr. Branthwaite commenced his duties, and this case he considered with the light of further experience was a preventable one. The second case was found on the morning after admission to be suffering from double pneumonia and delirium. The third occurred during his absence on a holiday.

During the past ten years I have been superintendent here, and not a single case of delirium tremens has developed among patients after admission. I have experienced three "scares" in cases where the patient passed a restless first night and when, in the morning after admission, the condition appeared to be threatening, but in each case I have been fortunate enough to get the patient to sleep in the early afternoon and have had no further trouble.

I have had to treat only one case of alcoholic epilepsy, this occurred some four months after admission of the patient. He had indulged in beer when on parole, and in his case quite a small quantity of liquor produced this condition. For this absence of complications I am largely indebted to Dr. Branthwaite, for I profited by his experience. All of Dr. Branthwaite's cases and all of mine during my first eight years were treated by absolute withdrawal of liquor. During the past two years I have very occasionally given to patients some brandy or whisky during the first day or two if they particularly desired it. This I have done not with any idea of preventing complications but merely as a placebo. A certain amount of spirit has been given in the form of pharmaceutical preparations, in spiritus ammoniæ aromaticus, for instance, but to the person who is accustomed to take alcohol by the pint or more daily a few drachms of spirit during the 24 hours is a negligible quantity.

Judging by the experience gained at the Dalrymple Home Retreat I am of opinion that delirium tremens, in the absence of surgical injuries or a disease such as pneumonia, is an avoidable complication when the patient can be kept under observation, and that under the same conditions those patients recover more rapidly whose liquor is stopped at once. I have admitted a few cases where delirium tremens had already just commenced, but with the exhibition of bromides in large doses and of hypnotics, among which chloral and paraldehyde are the most useful, sleep has been induced within 12 hours of admission. So that I cannot agree with the view which Dr. Hare is inclined to favour, that the best treatment of this condition is to withhold practically all drugs. The condition, in my opinion, requires energetic drug treatment.

I am, Sir, yours faithfully,
F. S. D. HOGG.

Dalrymple Home Retreat, Rickmansworth, April 13th, 1909.

HILLYER *v.* THE GOVERNORS OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—In reference to your report and comments on the above case may I crave the hospitality of your columns to tell all who may be interested that my solicitors have entered an appeal against Sir William Grantham's decision? By the help of friends I hope to make this a test case and obtain a legal ruling as to the liability of hospitals in such situations, for it must be admitted that this question is of grave importance not only to the authorities of hospitals but also to the general public who support these charities. May I add that I went into court under the impression that a jury would hear *all* the evidence and would be permitted to express their opinion? I am, Sir, yours faithfully,

London, April 12th, 1909. WILLIAM H. HILLYER

A CASE OF EXCISION OF THE SCAPULA.

To the Editor of THE LANCET.

SIR,—I was very pleased to read the letter of Mr. R. P. Rowlands in THE LANCET of Jan. 16th, calling my attention to a few discrepancies in my article on the above subject which was published in your journal of Jan. 9th.

In reply, I might state that my patient was able to abduct his arm voluntarily to an angle of 45 degrees, but on forced abduction to any degree beyond this limit he evinced much pain; but Mr. Rowlands's case was able to abduct his arm to a right angle only. It was originally the typist's error, when "90 degrees" were substituted for 45 degrees. Though the difference in the range of abduction in these two cases is only 45 degrees, yet I admit that every extra range of movement must certainly be of material advantage to any person. But the two cases under discussion are quite unlike each other: one was an enchondroma and the other a rapidly growing sarcoma. My subject was also able fully to flex, extend, and adduct his shoulder-joint, but internal and external rotation were only possible to a [illegible] must be remembered that active and passi[illegible] not commenced till the twenty-ninth day [illegible] owing to an attack of dysentery. Had these [illegible] commenced earlier he would have had a [illegible] abduction and internal and external rotation [illegible] that the utility of the joint had not been impaired I meant that the patient had a joint fairly strong and mobile to enable him to carry on his work as a coolie. But it was never meant that his joint was as good as the normal one.

With reference to my objections to leaving the glenoid socket and the coracoid process in one mass in innocent growths of the scapula, while admitting that the radiograms and the photographs support Mr. Rowlands's contention, I think it is not wise to draw any definite conclusions from the results of a single case. We must collect more materials and compare their results before we make any definite statements. While I hold the above view for the present, I must candidly admit that Mr. Rowlands's case is very instructive, and I [illegible] a suitable case should [illegible] the reasons mentioned [illegible] ticle published in the [illegible], 1908.

I am, Sir, yours faithfully,

H. B. MYLVAGANAM.

Bangalore, South India, March 13th, 1909.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Royal Victoria Infirmary.

THE Royal Victoria Infirmary was established in the year 1751 and the present report, dealing with the work of the infirmary for the year 1908, is the 158th since the foundation of the institution. The house committee point out that during the year the hospital was opened to its fullest extent. It will be remembered that the new buildings were opened by the King in July, 1906, and the work of the institution has gradually been transferred from its original home on the Forth banks. The occupation of the whole of the accommodation afforded by the buildings on the Moor Edge has, of course, led to a large increase in the number of patients treated and also to an increase in the ordinary expenditure. It is satisfactory to note that coincidently with an increase in the ordinary expenditure there has been an increase in the ordinary income, but the latter has not been sufficient to keep pace with the increased cost, so that the excess of expenditure over income is greater than it was in previous years. The house committee note that the cost per in-patient is less than in 1907 or 1906. "In order to meet the criticism that many patients are admitted into the hospital without sufficient care being taken to ascertain whether they are such persons as are entitled to receive the benefit of the charity, the house committee have appointed a subcommittee to consider the admission of patients. ...... During the present year they hope to collect figures and information to enable them to recommend some workable scheme which will solve to some extent this extremely difficult question." During the year several important changes have taken place on the staff. In August the resignation of Professor George Redmayne Murray was accepted with much regret and the house committee say that "during his tenure of office he has been distinguished for his courteous demeanour, profundity of knowledge, and devotion to the interests of the institution, and as a consequence has enjoyed the confidence and approbation of the committee and his colleagues and the gratitude of his patients." As I have already stated, Dr. Murray was appointed an honorary consulting physician to the infirmary on his accepting the invitation of the University of Manchester to become its professor of medicine. In March it was decided to appoint four assistant physicians instead of two as heretofore, and in November an honorary assistant was appointed to the ophthalmic department. As regards the finances of the infirmary, the total ordinary income in 1908 was £25,552 17*s.* This sum is larger than the figure for 1907 by £2683 0*s.* 10*d.* The subscribed income amounted to £21,588 2*s.* 1*d.*, which exceeded the income of 1907 by £3868 11*s.* 8*d.* The most [illegible] fact, probably, with regard to income is the [illegible] the workmen's subscriptions. In 1904 the [illegible] contributions totalled £4762 13*s.* 2*d.* In 1908 [illegible] was trebled and amounted to £14,219 12*s.* 3*d.* The [illegible]dinary expenditure amounted to £30,892 17*s.* 6*d.*, [illegible]xceeds the income for the same period by £5340, and is greater than the ordinary expenditure in 1907 by £3625 13*s.* The deficit at the end of the year 1908 is greater than the deficit at the end of 1907 by £942 12*s.* 2*d.* The cost per occupied bed, calculated on the total ordinary expenditure, was in 1908 £78 11*s.* 5*d.*, which is noticeably less than in 1907 and in 1906, when, on the same basis, the figures were £81 5*s.* 10¾*d.* and £81 5*s.* 1½*d.* respectively. When calculated upon the total ordinary expenditure, less the cost of out-patients and casuals, the cost per occupied bed was, in 1908, £74 14*s.* 6*d.*; in 1907, £77 5*s.* 10½*d.*; and in 1906, £75 17*s.* 7¾*d.* The number of patients admitted to the wards during the year was 7584, being 1103 more than in 1907, and the average daily number in the wards was 393·2, whereas in 1907 the average was 335·4, and in 1906, 251·8. The [illegible] on any one day was 425, which [illegible]er which can be accommodated. [illegible] committee state that it is their endeavour, so far as possible, to limit the number of occupied beds to 400 "in order that a margin of 25 may be kept available for any emergency that may arise." The average length of stay of each in-patient is greater than in 1907 or in 1906, the figures being 19·16 days in 1908, 18·9 days in 1907, and 18·7 days in 1906. The number of out-patients and casuals was also increased. In the year under review 37,324 out-patients were attended to and 23,468 casuals, the total attendances in the out-patient department (indoor and outdoor) being 104,725.

April 13th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Poisoning by Zinc.

POISONING by zinc is sufficiently rare to merit record when instances do [illegible] on the body [illegible] short period [illegible] chipped potatoes purchased at a shop in the town. The county analyst found traces of zinc in the contents of the girl's stomach, and the same metal was also found in samples of oil used for cooking the potatoes and in the potatoes themselves. The cooking-pans were coated with an alloy containing zinc, so that it is probable the action of the oil together with the process of cleansing the pans had enabled the zinc to become incorporated with the potatoes.

The Question of a Public Slaughter-house for Merthyr.

A suggestion to provide a public slaughter-house in Merthyr appears to have caused some alarm among the butchers of the town. At a meeting of the local Master Butchers' Association recently held the secretary of the National Federation of Meat Traders' Associations declared that the inconvenience, the increased expenditure, and the risks involved in the use of a public abattoir had resulted in the firm determination of master butchers to go to the dead meat market rather than use a public slaughter-house. He also stated that wherever these existed they were white elephants and involved the ratepayers in a considerable financial outlay for which there was no adequate return. This assertion is not quite in accordance with statements which have been made in recent literature on the subject. In Mr. Christopher Cash's work [1] a list is given of public slaughter-houses which, in reply to his inquiries, were stated to be a financial success. At Belfast the profit is said to be £800 per annum, and at Edinburgh over £900, while in several places the absence of any profit on the undertaking is attributed to the existence of private slaughter-houses which cannot be got rid of.

Glamorgan Water Board.

The Bill which is being promoted in the present session of Parliament by the Glamorgan county council, having for its main object the formation of a water board for the county, contains provisions empowering the board to purchase existing water undertakings. The largest of these in the county is that owned by the Pontypridd Waterworks Company which supplies the town of Pontypridd and about two-thirds of the Rhondda valleys. The principal gathering grounds of the company are at the head of the little Rhondda valley where there are storage reservoirs with a total capacity of 220,000,000 gallons. The supply has for some years been unsatisfactory, and one result of an action in the High Court brought by the Rhondda urban district council against the company in 1907 was an undertaking on the part of the latter to obtain Parliamentary powers for the construction of reservoirs in Breconshire. These powers were secured last year, and it is stated that terms have already been arranged for the transfer of the existing works and of the powers to construct others from the company to the water board in the event of the Bill of the county council becoming law.

Cardiff Medical School.

Although it is not at present possible to take the complete medical curriculum at the Cardiff College, the number of students from the Medical School who have already become qualified is 123. A great stimulus to the establishment of a Faculty of Medicine will no doubt be given by the recently issued report to the Treasury of the committee appointed to inquire into certain matters connected with the University of Wales and the Welsh University Colleges. Sir Donald MacAlister, President of the General Medical Council, who was a member of the committee, has appended a note to the report which has special reference to the Cardiff Medical School. He points out that the large international shipping trade of Cardiff makes it a natural centre for the study of tropical diseases, and he suggests that if a special school were organised in connexion with a completed medical department of the Cardiff College students and practitioners from other parts of the country would be attracted to it. He also expresses the opinion that Cardiff possesses all the requisites for a complete school of medicine, though he is careful to say that new buildings are a essential requisite, an assertion which no one will controvert.

Insanitary Structural Defects on New Vessels.

For several years past Dr. J. Howard-Jones, the medical officer of health for the borough, in his annual reports to the Newport port sanitary authority, has drawn attention to the hygienic defects which are to be found in quite new vessels, and the inspections which he made during last year disclose little, if any, improvement notwithstanding the fact that the vessels reported upon had been passed by the Board of Trade. In one instance the crew's quarters are described as little better than a hovel, so dark and so cut up into angular spaces that cleanliness was almost impossible. Such a dwelling, says Dr. Howard-Jones, would never be permitted by any sanitary authority to be occupied as a human habitation ashore. He further expresses the opinion that it is not at all surprising to find the type of man in our merchant service degenerating when sailors are compelled to live under such unsatisfactory conditions. From the record of nuisances and sanitary defects found during 1908 it appears that they were discovered in 13 per cent. of the 2593 British ships inspected and in 20 per cent. of the 994 foreign vessels. This proportion of defective conditions is higher than has been found in previous years both as regards British and foreign ships.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Maternity Hospital.

AT the annual meeting of the subscribers to the Glasgow Maternity Hospital the secretary of the institution showed that during the year in the various departments of the hospital the cases treated reached the large number of 4384. This is an increase of 210 cases in the indoor, 336 in the outdoor, and 98 in connexion with the Western Branch. Since the last annual meeting the new hospital has been opened and there is no doubt that it has the appreciation of the public and the confidence of the medical profession. It is satisfactory to note that the number of students enrolled has increased from 86 to 154 and that the pupil nurses have increased from 113 to 140. The financial statement shows that the expenditure for the year has exceeded the annual ordinary income by £1750.

Glasgow and West of Scotland Coöperation of Trained Nurses.

The sixteenth annual report of this association has just been issued and presents many points of interest. A coöperation such as this when well managed has proved a great boon to medical men and the general public of the West of Scotland, and has at the same time secured to nurses on the staff regular employment, adequate remuneration, and the advantages of a central home. The number of the nurses on the roll is 178. The number of cases attended during the past year was 1899, and the amount earned by the nurses £11,538. Since the establishment of the association in 1894 18,139 cases have been nursed and £108,039 have been earned. The system on which the scheme is worked is that at the termination of a case the nurse collects the fee and pays to the lady superintendent a percentage thereof, which is placed to the credit of a common fund out of which the yearly working expenses of the coöperation are defrayed. In the early years of the association 10 per cent. was contributed and this was afterwards reduced to 7½ per cent. During the year now completed the percentage has been raised. Nurses joining the coöperation pay 10 per cent. for the first two years, and after the first two years 7½ per cent. Nurses who have been seven years in the coöperation have the percentage reduced to 5 per cent. Nurses residing in the home when off duty make a quarterly payment of £1. which entitles them to sleeping-accommodation, board being charged at the rate of 12*s.* 6*d.* per week or 2*s.* 6*d.* per day. A sick fund has just been inaugurated in connexion with the association and to this all the nurses contribute £1 per annum, with the exception of four who are already members of the Royal National Fund. A bazaar was held last year to help this sick fund and by means of it the sum of £3523 was raised.

Pathological Laboratory for Asylums in the West of Scotland

A movement has been initiated for the establishment of a pathological laboratory in the West of Scotland on the same lines as the one at present in Edinburgh for carrying out pathological work in connexion with the asylums in the district. It is evident that the establishment of such an institution will undoubtedly be in the interests of medical science, but also in the interests of the patients in these asylums. The cost of carrying it on is estimated at £450 per annum, of which £300 would go in salary to the pathologist, the other £150 being applied to the various requirements of the institution. The committees of Woodilee and Gartloch Asylums under the Glasgow Lunacy Board have agreed to give an annual contribution of £50 each, and the directors of the Royal Gartnavel Asylum have promised to contribute handsomely to the scheme. It is expected that the remainder will be made up by the various other authorities interested.

The Municipalisation of the Sidlaw Sanatorium.

There is every prospect that the municipalisation of the Sidlaw Sanatorium will not be agreed to without a severe struggle. The matter was up for discussion at a meeting of the Harbur Trust on April 5th, when it was moved that the board resolve to oppose the town council acquiring the sanatorium. The Lord Provost, in reply, denied that the matter had been rushed. The ratepayers had not only been consulted but they had voluntarily sent representatives to urge upon the town council the advisability of acquiring the sanatorium. It was not proposed to treat more than 150 cases at any time. They were advised by their expert that in a year or two the city would be compelled to provide hospital accommodation for consumptives. They had an offer from the directors of a building that cost £25,000 and the offer of additional ground on very favourable terms. He thought that it would have been a mistake on the part of the council not to have jumped at the bargain The motion was carried by 18 votes to 3. The Chamber of Commerce at its monthly meeting on April 6th resolved to oppose by counsel and agents the acquisition of the sanatorium by the town council on the following grounds—viz., that due consideration had not been given to the financial burdens which would thereby devolve upon the community; that no reasonable opportunity had been afforded to the ratepayers to determine as to the advisability of such a step; and that sufficient information had not been furnished of the intentions of the town council in regard to the development of a scheme of such immense possibilities The secretary was instructed to intimate this resolution to the Harbur Trust and other public bodies with a view to joint action. Resolutions protesting against the scheme have been passed by several of the ward committees. It is believed that the Caledonian and North British Railway Companies will also take action. The Trades Council has unanimously decided to support the action of the town council.

University of Aberdeen: Graduation.

The spring graduation ceremony at the University of Aberdeen took place on April 6th in the Mitchell Hall, Marischal College. Principal Lang has been laid aside with illness for some weeks and Lord Strathcona came specially from London to preside in his place. This is the first occasion for a long period of years that a chancellor has fulfilled a like duty. Six gentlemen received the degree of M.D.; one that of Ch.M., seven that of D.P.H., and 37 those of M.B., Ch.B. At the close of the graduation ceremony Lord Strathcona delivered a short address on patriotism.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis Exhibition at the Rotunda Hospital, Dublin.

A TUBERCULOSIS Exhibition will be held in the Rotunda buildings on April 20th to 22nd under the presidency of Her Excellency the Countess of Aberdeen. Preliminary meetings for the purpose of making arrangements were held in the Rotunda on the 5th and 7th of this month. At the former it was proposed by Mr. Fletcher and seconded by Mr. E. H. Tweedy:—

[illegible] f the exhibition [illegible] National Health [illegible] power to add to [illegible]

Dr. M. F. Cox and Mr. John Mooney were appointed honorary treasurers, Dr. T. Donnelly, Dr. E. M. Fannin, and Mr. T. C. Harrington, M.P., honorary secretaries, and at the following meeting of the executive committee (on April 7th) the various sections of the exhibition were allocated to [illegible] follows: Pathological Sec- [illegible] Veterinary Section: Mr. [illegible] J. Wilkinson. Statistical Section: Sir R. E. Matheson. Literature Section: Dr. A. G. Boyd. Appliances Section: Sir W. J. Thompson. Hygiene Section: Mr. George Fletcher, Dr. R. J. Rowlette, and Professor F. T. Heuston. Food Section: Professor W. H. Thompson. Domestic Science Section: Mrs. Rushton, Miss Fletcher, and Miss McNeill. Her Excellency then announced that Dr. E. W. Hope, superintendent medical officer of health of Liverpool, would deliver a lecture on Tuesday, April 20th, and that Dr. Philips would lecture on the following evening. It was also decided that popular lectures should be delivered every evening, and that demonstrations of exhibits should be given frequently during the day.

Benn Ulster Eye, Ear, and Throat Hospital.

From the annual report presented at the meeting of the supporters of this institution on April 8th it appears that 3539 new patients were treated during 1908, while 340 were taken into the wards. Over 60 operations for cataract were done during the year. The debt on the hospital has been increased to £244 5*s.* 5*d.* Special reference was made to the much regretted death of Dr. R. Allen, one of the assistant surgeons, in whose place Dr. Henry Hanna has been appointed; while Dr. Isaac A. Davidson and Dr. J. McCredy have been appointed clinical assistants and Dr. F. C. Smyth anæsthetist.

The Belfast Health Commission.

The Local Government Board (advised by the Law Officers of the Crown) has demanded from the city corporation of Belfast the sum of £1431 10*s.* 10*d.* for the cost of the late Health Commission. Two counsel advise the corporation that it is not liable for the sum of £608, being the amount paid respectively to the chairman and two other members of the Commission who were not officials of the Irish Local Government Board. The matter is under consideration; the two counsel representing the corporation, in the meantime, are to look into the advice of the Crown law officers, as given to the Local Government Board.

Overcrowding of Ulster Asylums.

From the tenth annual report of the Monaghan and Cavan Lunatic Asylum it appears that there were 858 inmates (460 men and 398 women). 179 were admitted during the year, and the total number under treatment during the year was 1030. The numbers remaining at the close of the year were 33 more than those in the house at the close of the previous year. The new detachable block to accommodate 120 patients has been occupied since April last, and even with this accommodation utilised there are still 89 patients in excess of the legitimate space. At the monthly meeting of [illegible] ylum, held on April 8th, the [illegible] accommodation to relieve [illegible] as again under consideration but was adjourned.

April 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Foreign Bodies Removed from the Œsophagus.

AT a meeting of the Society of Medicine held on March 27th M. Guisez showed 18 foreign bodies which had been removed from the œsophagus by œsophagoscopy, such as pieces of bone, fish bones, coins, buttons, and at least five artificial tooth plates. Thanks to instrumental perfection and the employment of dilating tubes, the extremity of which can open and protect the walls of the œsophagus at the moment of extraction, operation during the last two years has been invariably successful.

Poisoning by Subnitrate of Bismuth.

M. Léon, at a meeting of the Hospitals Medical Society held on March 27th, drew attention to certain risks which might occur from the use of bismuth subnitrate as laid down by the new Codex. The subnitrate of the Codex of 1884 contained 17 per cent. of nitric acid, while that of the new Codex contains 24 per cent. If these two different preparations of bismuth are acted upon by a hyperacid gastric juice, the bismuth salt from the new Codex forms a solution of nitric acid twice as strong as that from the old Codex. M. Léon suggested the employment of a neutral subnitrate prepared by washing the acid subnitrate in boiling water containing some carbonate of sodium. The salt thus obtained only contained some 4 per cent. of nitric acid.

Injections of Strophanthin.

At the same meeting of the same society M. Vaquez and M. Lecomte communicated a paper in which they said that they had obtained excellent results in cardiac insufficiency by injecting one milligramme of strophanthin into the veins every two or three days. The asystoly lessened, the œdema disappeared, copious diuresis was set up, and the dilated heart returned to its normal dimensions. While recognising the dangers which might occur by this method of medication, the two observers said that it should not be neglected altogether, but that it should be employed only in cases where other drugs have been without results. Only very small doses should be used and in case of renal insufficiency the condition must not be due to a definite affection of the kidneys.

The Use of Cerebral Extract in Nervous Maladies.

At a meeting of the Academy of Medicine held on March 30th M Page said that he had been using extract of cerebral substance in cases of nervous disease. Constantin Paul had already employed this method but with very variable results. He used an extract of the whole brain of the sheep. M. Page uses an oily extract (*extrait gras*) which according to him contains an antitoxin. The effect of injecting this substance is to influence the arterial pressure and to diminish the amount of phosphates excreted in the urine. At the same time the appetite of the patient improves, he puts on flesh, and his strength is increased. In 20 cases in which this method of treatment was used, mostly those of neurasthenia, the length of treatment occupied only half the time of the usual methods.

The Treatment of Gout by Puncture of the Articulations.

At a meeting of the Therapeutical Society held on March 24th M. Lumière and M. Gelibert communicated a paper in which they said that for the last five years they had systematically used puncture in the case of all large gouty joints which were the seat of an effusion, more especially in the knee. They had obtained the following results. On the one hand the pain rapidly disappeared, the temperature fell to normal, and the attack was notably shortened; on the other hand, the fluid drawn off contained no appreciable quantity of uric acid or of urates. It was, however, extremely poisonous and brought about a marked rise in the temperature. These observations put into the hands of the physician a new curative method at once simple, rapid, and efficacious, and they introduced quite new ideas into the pathogeny of gout, especially as concerns ideas held up to the present as to the rôle played by uric acid in the gouty diathesis.

A Parasite of the Vine and Cancer.

At a meeting of the Academy of Sciences held on March 29th M. d'Arsonval related some interesting experiments originally begun by Charrin and carried on by M. le Play. By injecting a certain parasite from the vine into the peritoneal cavity of animals M. le Play found that he brought about the growth of tumours the aspect of which closely resembled that of a cancerous growth. The parasite localised itself in the liver. If it were injected into the blood-stream its vitality was diminished, but sooner or later it always infected the liver, which appears to be its chosen habitat.

Opium in Madagascar.

At the instigation of the Governor-General of Madagascar the Colonial Minister has just issued a decree for strictly regulating the importation, sale, or storage of opium in that colony. A decree of August 31st, 1908, had already forbidden the existence of opium-smoking dens, but it was found to be useless unless the authorities could exercise some control over the importation of the drug.

Shakespearian Toxicology.

For the most part the heroes and heroines of Shakespeare, when they do die, perish by a violent death, and Dr. A. Cartaz has been studying the methods of these deaths. The ghost of Hamlet's father revealed to his son that he, the father, had died from *jus de jusquiame* (juice of cursed hebenon). Dr. Cartaz argues that henbane juice, unless some other and corrosive substance is added to it, could not have such a fatal effect. Moreover, whatever hebenon may mean, whether it be henbane or yew or broom, poisoning by way of the ear is hardly possible, and so Dr. Cartaz says that (to produce the effect described) the poison must have been given either at the same time or before by the mouth. Possibly the word hebenon is used in the generic sense of any poison bringing about confusion and dulness of the senses. This explanation, however, does not help us to understand how the poisoning can be produced by dropping it into the ear. As regards the slumber of Juliet Dr. Cartaz thinks that Friar Lawrence used mandragora to put that heroine to sleep, but he is astonished that the slumber lasted so long, and he thinks that some hypnotic influence must be invoked in addition to the poison.

April 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Infective Agent of Trachoma.

Professor Greef of Berlin, writing to the *Deutsche Medizinische Wochenschrift*, reports that he has detected the infective agent of trachoma. These bodies are small and round, much smaller than the smallest micrococci hitherto known. They may be stained very strongly after Giemsa's method but not after Gram's method, and appear sometimes more violet, sometimes more reddish. They are surrounded by a distinctly light circle; and under the highest powers it is seen that they are not circular but more oval like bacteria with rounded edges and they tend to congregate like diplococci. In the later stages of the disease they are present in crowds within the cells. They were found in the follicle, both within and without the cells, in the epithelium, and in the discharged fluid. By using other diseases of the eyes and normal eyes as controls it was ascertained that the above bodies were not present except only in trachoma. The demonstration of these bodies is difficult and the procedure described by Professor Greef is rather complicated. Fresh cases without previous treatment must be taken, the bodies in question being no longer visible after some days' treatment by caustics. They have by that time disappeared from the superficial layers of the tissues but continue to be present within the deeper layer where they increase and produce relapses.

Diabetes in Infants.

At a recent meeting of the Verein für Innere Medicin Dr. Langstein read a paper on Diabetes in Infants. He showed a baby eight months old without any apparent morbid condition. The child was quite well till the age of six months when the temperature rose and slight digestive troubles developed. The mother afterwards remarked that the napkins moistened by the baby's urine became stiff, and that the child had an enormous thirst. On examination the urine showed 3·5 per cent. of sugar which was not galactose but glucose, so that the case proved to be really diabetes. The daily quantity of urine was on an average 880 grammes, containing 66 grammes of sugar. The patient was accordingly fed by a milk specially prepared as follows. The casein and fat of one and a half litres of ordinary milk were precipitated by rennet essence, the sugar was then removed by washing the coagulated mass, and the latter was then pressed through a fine sieve into a mixture of 200 grammes of whey and 1300 grammes of water. The mixture obtained in this way contained only eight grammes of sugar, but much fat and albumin, and saccharin was added to make it palatable. By the administration of the above mixture the daily quantity of sugar in the urine decreased to eight grammes. Concerning the etiology, it is remarkable that the mother had given to the baby since the sixth month daily 200 grammes of sugar. Cases of diabetes in infants are very rare; and many of the instances described in the medical literature are probably not to be trusted.

The Relation between the Hypophysis Cerebri and Ovaries.

Dr. Thumim recently reported the case of a woman in whom after irregularities and eventually complete cessation of menstruation the first symptoms of acromegaly developed. The patient, a singer, had lost her voice, but on laryngoscopical examination only an increase of the thyroid cartilages was observed. An acromegalic condition developed, [illegible] alteration of the sella turcica was [illegible] cerebri was administered in tablet [illegible] t the disease has not of late progressed. The ovaries were found to be atrophic, and Dr. Thumim suggested that this atrophy had produced a hypertrophy of the hypophysis cerebri leading to acromegaly.

The Medical Women of Berlin.

The medical women of Berlin have recently formed an association of their own. They intend to establish a hospital of which the staff will consist exclusively of women and include wards for the indigent classes, together with paying wards for well-to-do patients. The number of medical women has increased in Berlin since women were admitted to the State examination and so obtained an opportunity to become duly qualified. Nearly every one of the numerous medical societies of Berlin now includes medical women although their active part in the proceedings is not marked. In the recent medical directory 26 medical women are registered in Berlin apart from those ladies who previously to the admittance of women to the German examination have taken their degree in Switzerland and practise under that diploma.

April 12th.

DONATIONS AND BEQUESTS.—Mr. Conway Rose of Chard, Somerset, has forwarded £1000 to the committee of the Royal Alexandra Hospital, Rhyl, towards the building fund for a new wing.—The trustees of the late Hon. Sheriff Anderson have intimated to the board of the Hawick Cottage Hospital that they will give a donation of £500 for the building and furnishing of another private ward to be named the Anderson Ward.

Obituary.

ARTHUR GAMGEE, M.D. EDIN., F.R.C.P. LOND., F.R.S.,

EMERITUS PROFESSOR OF PHYSIOLOGY, VICTORIA UNIVERSITY, MANCHESTER.

MANY friends of Dr. Arthur Gamgee, both in this country and abroad, where he was widely known, will hear with the deepest regret of his unexpected death in Paris on March 29th. This was due to congestion of the lungs following an attack of influenza. His journey to Paris, destined to end so sadly, was undertaken in order to meet his life-long friend Professor Hugo Kronecker of Berne, who, on finding him so ill, arranged for his removal into the nursing home where he died, though fortunately not before his wife and daughters had reached Paris. He was in his sixty-eighth year.

Dr. Arthur Gamgee was born in 1841 in Edinburgh, and was the younger son of Joseph Gamgee, a distinguished veterinary surgeon and pathologist, whose researches, particularly those with regard to rinderpest, attracted a large amount of notice both in England and on the Continent. His elder brother, Joseph Sampson Gamgee, whose life-work came to be so closely associated with the Birmingham General Hospital, was an exceptionally brilliant man, a facile linguist, a fluent speaker, a lucid writer on medical subjects, who acquired a great surgical reputation, especially by the introduction of improved methods for the treatment of wounds in the days when even the word bacteriology was unknown. This brother died in his fifty-ninth year in 1886.

Educated at University College School, Arthur Gamgee was entered as a medical student at Edinburgh University. Here at the outset of his life he showed a special interest in physiological work, particularly in physiological chemistry, as is evidenced by his inaugural thesis on "Contributions to the Chemistry [illegible]
the medical [illegible]
a gold medal [illegible]
work, may be found in the *British and Foreign Medico-Chirurgical Review*.[1] From 1863 to 1869 he held an appointment under Dr. Maclagan, who was professor of medical jurisprudence in the University, but his natural leanings were towards scientific research, and numerous papers, of which the most interesting are those on the Action of Nitrites on Blood (1868), and with J. Dewar on the Constitution and Physiological Relations of Cystine (1871), gave evidence of his marked ability to investigate abstruse problems in physiological chemistry. In the first of these papers he described elaborately every important point in the history of methæmoglobin, its crystalline shape, its power of absorbing and retaining oxygen—facts rediscovered years later by Hüfner. Gamgee was only mistaken in not recognising that other agents besides nitrites exerted the same action on hæmoglobin. The research on cystine was no less important, though the actual constitution determined for this amino-acid has undergone some modification by the subsequent researches of Friedmann. In 1872 Dr. Gamgee was elected to the Royal Society. His age at that time was 31, and a year later he became the first Brackenbury Professor of Physiology in the Owens College, Manchester. His connexion with Manchester, during which time he shared the work of those who were actively striving for a charter which should convert the College into the Victoria University, lasted for 12 years, and it is during this period that Gamgee, by his enthusiasm, his tireless energy, and sound judgment of the real relations which should subsist between those who teach and those who learn, accomplished what will prove to be the best remembered work of his life. As dean it fell to him to found the school in his own subject, and his output of original work in physiology and pharmacology during that time has never since been approached. His own attitude as a teacher may be gathered from his introductory address in 1883, 22 years after the foundation and ten years after the removal of the College from Kay-street to the present site, where he says that "popular courses of lectures cannot in any sense constitute academic teaching. ...... But the governors and professors were imbued with the spirit that the College which they were fostering must above all and before all be a place where learning is studied and taught for its own sake; and that in order to exert that influence, which great academic institutions have exercised in the past, it must be not merely a place where routine teaching is carried out, but a centre in which learning is added to by the labours of those who teach —a place of research, a centre of light. No university ought to be imbued with a purely utilitarian view of education."

Looking back on that period it can be clearly seen that Owens College numbered among its professors men who made the College famous all over England—Roscoe, Balfour Stewart, Stanley Jevons exerted an immense influence throughout the country. In our own quieter times it is difficult to realise that these men were, together with Huxley and Tyndall, the real pioneers who unceasingly laboured, and successfully laboured, to place the study of science on a level with the teaching of the older universities. In this connexion it is worth remembering that not only by the publication of primers and elementary text-books, but by the courses of evening "Science Lectures for the People," which were almost entirely due to Sir Henry Roscoe, those who had the best interests of science at heart were actually engaged in slowly convincing a hostile majority that the knowledge obtained by experimental work was of vital importance to the country. These lectures, initiated in 1866, continued until 1880 and were given by Huxley, Tyndall, W. K. Clifford, W. Pengelly, Spottiswood, Sir Norman Lockyer, and others, as well as by those more closely connected with the Owens College. The real value of this work, in which science instruction was given in a plain but scientific form, can scarcely be overestimated, for the object of these popular lectures was to arouse an interest in the study and pursuits of science, rather than to convey a large amount of information. Indeed, at that time science had to fight both for existence and recognition.

This short tribute to those to whom the early success of the Owens College was due enables us to see clearly the environment of Dr. Gamgee while at Manchester. The work by which he will be chiefly remembered was done during those years and with the rest he loyally worked for the success of his College. The science of physiology in this country was practically non-existent until 1873. It is quite true that there were physiologists, and some of these of European reputation, but the subject was neither taught nor studied in the only way that is possible, by experimental methods. Prior to this date there was a single professor of physiology in England. A history of the rapid growth of this science, the British school of which now takes rank with that of any on the Continent or in America, cannot be given here, but two publications—the "Handbook of the Physiological Laboratory," by Brunton, Klein, Burdon Sanderson, and Michael Foster, which appeared in 1873, and in particular the "Text-book of Physiology," by Foster in 1877—completely revolutionised the existing conceptions as to the scope and value of this science. The teachers of physiology at Cambridge, University College, London, and the Owens College were really the three men who by their influence primarily attracted students to their laboratories in which the real study of physiology was carried out. Instead of vague unmeaning speculations which filled page after page of older books, the subject, in the hands of Burdon Sanderson, Foster, and Gamgee, under the influence of Carl Ludwig, Kühne, and Hoppe-Seyler, became a laboratory study, and one which it was clear could only be advanced by the application of accurate chemical and physical methods to physiological problems. In this development Dr. Gamgee took his part, and rapidly showed that he possessed a richly endowed mind, a scholarly interest in his subject, and an exceptional knowledge of physical and chemical methods. As Brackenbury professor, as Fullerian professor of physiology in the Royal Institution from 1882 to 1885, as a frequent lecturer in Manchester and in London to popular audiences, his energy and enthusiasm found full play. In 1882, the year in which science had to suffer the loss of Charles Darwin, and, from an accident in the Alps, of F. M. Balfour, Dr. Gamgee was president of the Biological Section of the British Association which met at Southampton, where Dr. C. W. Siemens succeeded Lord Avebury as president. It was the year that the late Professor Moseley lectured on "Pelagic Life" and Lord Kelvin on "Tides and Tide Calculating Machines."

---

[1] London, 1864, vol. xxxiii.

Dr. Gamgee chose for his address the Growth of our Knowledge of Secretion, and it is certainly one of the most erudite and masterly expositions of this part of physiology which have ever been written. It fell to his lot to speak of the loss of Darwin and also of Balfour, who, like Mayow, Bichat, Gerhardt, and W. K. Clifford, died before he was 40. In this address we also learn of the influence which John Goodsir exercised upon his early work, a teacher for whom he had the warmest affection. It has long ceased to be possible to judge of the religious belief of any man by his manner of life or even his attitude towards orthodox religion, and it is therefore of interest to quote from this address where Dr. Gamgee refers to Darwin: "It is impossible to study the writings of Darwin, and especially that one in which he treats of the 'Descent of Man,' without recognising an undercurrent of reverent sentiment which in one or two places finds expression in words telling us that man differs from the animal creation if not in physical characteristics which cannot be bridged over, at least in moral attributes and in 'the ennobling belief in God' by his power of forming that conception of the Deity which to use Darwin's own words is 'the grand idea of God hating sin and loving righteousness.' "[2] To quote further from this address, which contains so much that enables us to understand Dr. Gamgee's views, after pointing out that Goodsir was mistaken in some of his ideas as to the function of cells in the process of secretion, he pays a tribute to his teacher whose mind he regarded as resembling that of Johannes Müller. He says: "Goodsir was a master who, if judged by the low standard of fitness to instruct the great majority of his pupils in such a manner as to enable them to successfully pass examinations, would occupy no exalted position. He possessed, however, the far rarer power of instilling into the minds of the best of his pupils that love of original inquiry and that deep regard for truth which are the chief incentives to all scientific research of any value."

It was during his years at Manchester that Dr. Gamgee translated Hermann's "Lehrbuch der Physiologie." This translation from the fifth German edition came out in 1875. A second edition with additions and illustrations appeared in 1877. His greatest work, however, beyond doubt, and one which was destined to make Dr. Gamgee's name widely known, was the "Text-book of the Physiological Chemistry of the Animal Body, including an Account of the Chemical Changes occurring in Disease." The book, published in 1880, was dedicated to Sir Robert Christison, the author, in offering his tribute of admiration and regard, stating that "This intention has always been present with me, and this thought has added pleasure to what has truly been a congenial task." This volume involved an immense amount of original research and patient work, and though nearly 30 years have elapsed it still remains a solid monument to Dr. Gamgee and a lasting credit to British physiology. In its treatment of the subject it stands quite alone, unassailable as one of the most painstaking and originally conceived works in scientific literature. It is true enough that no one could have foreseen the immense development which organic chemistry has undergone. It is doubtful whether the advances made in organic and physical chemistry during the last two decades will be paralleled in another quarter of a century. Then physical chemistry was almost non-existent, organic chemistry was in its infancy, and synthetic chemistry was being founded by Berthelot. But the value of this work is in no way impaired by subsequent researches. It was, and will continue to be, the best exposition of the subject as this appeared to the author, a book strictly concerned with physiological chemistry as contrasted with organic chemistry that has a physiological bearing. The subject is treated from the point of view of the biologist and physician rather than the chemist, the arrangement of the subject is physiological rather than chemical, and for the first time a book was produced in the English language available both for the study and the laboratory. Marked literary excellence characterises the book: it is able to be easily read by students or by teachers. Above all, the value of accurate experimental work comes out on almost every page; as one of those who reviewed the book has said, the author has kept before him the saying, "*Chymia egregia ancilla medicinæ, non alia pejor domina.*" In 1880 the importance of chemical research in the direction of an aid to pathology was almost unknown, and this book was at once an indispensable and exhaustive contribution to English science and medicine. A second volume which constituted an independent and complete treatise on the "Physiological Chemistry of Digestion" appeared 13 years later. This, like its predecessor, was written not so much from the standpoint of a pure chemist as from that of a physiologist; all parts of the subject which are of interest to the pathologist, pharmacologist, and the scientific physician are treated with especial care. That part of the volume which deals with the bile, jaundice, and the formation of gall-stones stands out with particular clearness on account of its excellence. While engaged on this volume the author continued to collect papers and re-wrote the first volume which was out of print. The whole work, though incomplete, remains as evidence of the thoroughness which almost amounted to pedantry with which Dr. Gamgee carried out his work; his industry, his single-heartedness of purpose, and his absorbing love of scientific research can be appreciated from these two books. By these he will be remembered, for his numerous original papers are naturally only known to comparatively few students.

In 1885 Dr. Gamgee left Manchester, was appointed assistant physician at St. George's Hospital in 1889, and lectured on pharmacology and materia medica in the medical school. He resigned from ill-health, resumed his scientific work in Cambridge, finishing later in Berne the second volume of the "Text-book of Physiological Chemistry." He determined to work and live abroad, practising as a consulting physician first at Lausanne and subsequently for several years at Montreux. In his spare time he worked actively on those absorption bands of hæmoglobin and its derivatives which are to be found in the ultra-violet portions of the spectrum (Soret's bands). While at Montreux, where he fitted up a laboratory in the basement of his house, he continued those researches which were to form the substance of his Croonian lecture before the Royal Society in 1902, on Certain Chemical and Physical Properties of Hæmoglobin. This subject, treated so admirably, had been the design of his investigations for years, and we must still look to his contribution to Schäfer's "Text-book of Physiology" for the most exact and painstaking account of "Hæmoglobin: its Compounds and the Principal Products of its Decomposition," which *exists* in English or, indeed, in any other language. In his researches on the blood pigment he demonstrated that this, like silicic acid, could exist in a colloidal state, hæmoglobin falling as a red cloud through a colourless liquid in the anodic compartment of an electrolytic cell. It is in this colloidal state that hæmoglobin probably exists within the red corpuscles. Other facts first discovered by Dr. Gamgee are the paramagnetic behaviour of hæmin and the dextro-rotatory properties of hæmoglobin.

In the autumn of 1902 Dr. Gamgee was invited to America, visiting the laboratories of New York, Baltimore, Philadelphia, and Harvard. The purpose of this visit was to enable him to take a complete survey of our present knowledge of nutrition. The difficulties in the way of completing this work were far beyond what he had anticipated, and his medical work at Montreux had grown so as to leave him but little time for a work, which could only be done with assistance and in proximity to a thoroughly equipped library. In the spring of 1903 he revisited America, previous to which he had just received the Hon. LL.D. of Edinburgh, a city which he loved more than any in the world and one which gave him a warm welcome on this occasion. From the time of his return to Switzerland his scientific work begun there, and subsequently carried out at Cambridge and in the Physiological Laboratory of the University of London, was concerned with the realisation of an idea conceived much earlier—the continuous registration of the variations in temperature of the animal body. By means of a photographic recorder a continuous registration, and by the thread-recorder devised by Mr. Horace Darwin a quasi-continuous record, can be obtained by the use of thermo-electric couples and thermostats which are capable of being maintained at an absolutely constant temperature. Dr. Gamgee's last published paper in the *Philosophical Transactions* of the Royal Society in 1908 contains a full account of the methods which he had devised for studying the fluctuations of the body temperature in health and disease, together with a full account of the history of medical thermometry from the time of Sanctorius

ARTHUR GAMGEE, M.D. EDIN., F.R.C.P. LOND., F.R.S.

(From a photograph by Messrs. Elliot and Fry.)

to the present day. This idea of being able to graphically register temperature variations was solved by Dr. Gamgee, and this work he believed in the future was likely to play an important part in the diagnosis and treatment of disease. And it is certain that if the records of temperatures taken several times a day with thermometers are of value, a fact traversed by no one, then a practical method for registering the diurnal curve of temperature must be of far-reaching importance, and doubtless there is a wide field of research open to those who will employ such a method as an adjunct to clinical study. An advance in method which has reference to the general metabolic processes of the body cannot fail to add to our knowledge of the phenomena both of health and of disease.

In 1908 Dr. Gamgee received the Hon. D.Sc. of the Victoria University and most eulogistic references to his work were made by the Principal. "An interpreter of the work of German physiologists, he has as an investigator long since repaid the debt to his brethren of that nationality, who in their turn are now glad to have at their command and in their tongue the records of his life-long researches, and I claim that no one has shown greater skill or a more subtle genius in the field of research than the physiologist whom I bring before you." Last year he represented the Royal Society on the occasion of the celebration of Haller's bicentenary at Berne, and during the last few months he was actively engaged in furthering the success of the International Congress of Applied Chemistry, which meets in London on May 27th. He was vice-president of the Physiological Chemistry Section.

Men like Professor Arthur Gamgee are difficult to place in any exact order in the hierarchy of physicians. His clinical work was dwarfed by the range and intensity of his scientific labours, and these, in their turn, were so original that their scope and value could not be immediately estimated by his medical colleagues. In our view Gamgee's resolute intention to make his research work have a practical bearing upon pathology, pharmacology, and therapeutics generally (see the complete bibliography of his writings appended to this notice) secures for him an extraordinarily high place among the leaders of medicine, a place which later development in our science will only serve to confirm or even further to elevate. He was an excellent linguist, possessed of a most retentive memory, a thoughtful student of the history of many branches of science, and an excellent classical scholar. Quoting from his favourite author, we may say of him: "Nonne vobis videtur animus is, qui plus cernat et longius, videre, se ad meliora proficisci; ille autem, cujus obtusior sit acies, non videre?" He preserved throughout his life his enthusiastic love for scientific work, which led him to give his time ungrudgingly to research, and he dwelt in the atmosphere which envelops those who care for knowledge for its own sake. Art, literature, science, each demands much of a man. To science Dr. Gamgee devoted his life. In return for this, in his work and in the affection, not only of his own family, to whom he was so dear, but in the genuine affection which so many felt for him, he must have had his reward. To those who knew him intimately, could understand his aims, his single-heartedness, and the complete simplicity of his nature, which was almost like that of a child, his loss has been severe. Of a most affectionate disposition and of a sanguine temperament he may not always have chosen to display these qualities to others. He has not lived to complete his work; it was ordained otherwise. In 1875 he married the daughter of Mr. J. Proctor Clark. This lady and two daughters survive him, and to them we offer our deep sympathy in their bereavement.

BIBLIOGRAPHY.

Systematic Works by Dr. Gamgee.

Hermann's Elements of Human Physiology. Translated and edited from the fifth German edition, Smith & Elder, 1875. CLAUDIUS GALEN WHEELHOUSE, F.R.C.S. ENG., LL.D. McGILL, D.SC. LEEDS,

CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY.

WE deeply regret to announce the death, at his residence at Filey, on Good Friday, April 9th, of Mr. Claudius Galen Wheelhouse, the well-known surgeon. His death was not unexpected, for he had suffered for some weeks in a serious manner from attacks of cardiac syncope, but until quite the end he bore his burden of years bravely.

Claudius Galen Wheelhouse was born at Snaith in 1827, where his father, Mr. James Wheelhouse, practised as a surgeon. At the age of seven he entered the country branch of Christ's Hospital at Hertford, and later passed into the main school where he remained until, at the age of 16, when he made up his mind to follow in his father's footsteps and become a medical practitioner. At the age of 16 he was accordingly apprenticed to a firm of medical men in Ollerton, Notts, with whom he resided as a pupil for three or four years, and from whom he received such kindness and excellent instruction that he always advocated a system of apprenticeship for those entering the medical profession long after such a system had become practically obsolete. In 1846, being now 19 years of age, young Wheelhouse entered the Leeds School of Medicine, where he remained for three years until he obtained the diploma of M.R.C.S. Eng. in May, 1849. In the autumn of that year he left England in the professional charge of a party of noblemen, and in the course of a long and interesting journey visited Greece, Turkey, Egypt, Syria, and Palestine, taking with him one of the first photographic cameras that ever left England, which he used with considerable success, the resulting pictures being in the possession of his family.

In 1851 Mr. Wheelhouse became the partner in the well-established practice in Leeds of Mr. Joseph Garlick, and in the same year he was appointed demonstrator of anatomy in the Leeds Medical School and surgeon to the Leeds Public Dispensary. He now became an exceedingly busy man, being engaged at the same time in all the cares of general practice while pursuing with ardour the purely scientific side of his profession as a highly successful teacher. In 1864 he became a Fellow of the Royal College of Surgeons of England, and about this time he severed his connexion with the Public Dispensary, being elected surgeon to the Leeds Infirmary. To his educational work Mr. Wheelhouse showed the greatest devotion. He lectured in turn upon anatomy and surgery and took large classes of private pupils, with whom he was extraordinarily successful. As the well-informed writer of the obituary notice in the *Yorkshire Post* says: "For many years few of the pupils of the Leeds School of Medicine presented themselves for examination at the Royal College of Surgeons until they had his assurance that they were fit to do so, and even to this day many of his old pupils will remember with gratitude the care he took in their preparation. The high position to which the Leeds School of Medicine attained was to a very large extent due to the unremitting zeal which Mr. Wheelhouse took in nursing the institution through its early difficulties, and he is pronounced by the students of that day to have been one of the best teachers of anatomy, physiology, and surgery that the school ever possessed."

We can trace in Mr. Wheelhouse's extremely successful career during the next 20 years of his life why he was universally regarded in the profession as the most typical representative of general professional interests in the country. And we can see also why he himself was so ardent a champion of the rights of the general practitioner and so earnest in his declarations that the general practitioner must always be the backbone of our calling. He was himself in general practice while making his influence felt in a continually increasing manner both as surgeon and teacher, and he always attributed his success to the thorough manner in which he had been grounded in the elements of his calling by his apprenticeship as a youth. He carried into the practice of surgery the thoroughness and accuracy which he owed to his long anatomical studies, together with an attention to detail that was the outcome of much bedside experience. These qualities are well shown in the operation which bears his name. External urethrotomy appears to have been first performed by Mariannus Sanctus in 1554, though many have ascribed it to Jérome Cardanus and Durante Saccachi, but it was almost forgotten till 1844 when Syme introduced his operation for permeable strictures. For strictures through which it was not possible to pass any instrument Cock's puncture remained the sole resource until Wheelhouse in 1876 published his method of external urethrotomy. Until this operation was known, any attempt to reach the stricture by dissection was very likely to fail, for the surgeon was entirely without a guide and he was much more likely to miss the urethra than to find it. Wheelhouse claimed that his method rendered an operation, confessedly one of the most difficult in surgery, a comparatively easy one, giving results both immediately and ultimately more favourable than ever seen before. The operation remains to the present day the best method of dealing with most cases of impermeable strictures of the urethra; several modifications have been made in the details of the operation but no important alteration has been effected. The advance of surgery in the direction of asepsis renders it nowadays a much simpler operation to cut down directly on to the stricture, to dissect it out, and to suture the two ends of the urethra, for the septic risks have been much reduced, but this method of excision of the stricture will probably for long be reserved for the exceptional case, while Wheelhouse's [illegible]ation, perhaps modified somewhat, will continue to [illegible] tion of choice for impermeable strictures. To
results it is necessary to pay attention t
instructions to open the urethra not at the
but at least a quarter of an inch in front of it

Turning now from the scientific to the
Wheelhouse's busy career we find him as an i
at the board of the General Medical Counc
supporter of the British Medical Associati
held at different times the chief offices. In
Address in Surgery at the meeting at Bath, a
1884 he was President of the Council of the
in 1889 he was President of the Association
meeting was held at Leeds. In referring
address on that occasion, which dealt wit
medical education and examinations, w

practical man. In 1897 he received the g
British Medical Association, and in the sa
annual meeting of the Association was hel
with Lord Lister, was among the recipient
degree of LL D. from the McGill Universit

In 1886, when the principle of direct re
the General Medical Council was first conc
with his firm friend the late Dr. Glover and
were the selected representatives of the
for England. Wheelhouse was again cho
two colleagues for a second term of offi
uninterruptedly for ten years upon the Cou
time he served with the best of his great a
the general practitioner. There was nothing
about him, so that all his words and actions
to a certain type of reformer, but in the
was always listened to with respect. I
profession was sharply divided by the vex
registration of midwives and Wheelhous
offer himself for re-election; nor could h
reconsider this decision when in the f
unexpected vacancy in the direct repre
profession occurred. On the inauguration
of Leeds in 1904 Mr. Wheelhouse receiv
the Marquis of Ripon, Chancellor of t
degree of D.Sc. as a recognition of h
cause of medical education in Leeds, and
have been a singularly gratifying one to
the successful outcome of labours to w
but distinguished group of colleagues had
for many years.

One other side of Mr. Wheelhouse's va
deserves mention, as it shows him in his
of the kindest of men—we refer to his l
with the West Riding Charitable Society.
ship with Mr. Garlick, who was secretary t
Charitable Society from its foundation in
became interested in its work, and after
partner he continued to assist the new se
finally succeeded. The work was cong
w himself into it with extraordina

ervices to it as secretary and treasurer for 25 years 300 of his [illegible] him at the annual dinner [illegible] and chain, a tea service, [illegible] e subscribers in an album. [illegible] e peace for the East Riding ivision of Yorkshire, and as magistrate, school manager, hurchwarden, and the holder of other public offices contributed in no small measure to the welfare of the county ith which he was associated.

In this brief notice of the career of Mr. Wheelhouse we ave endeavoured to show the consistent honesty and mplicity of the man. He had fine ideals of what the edical life should be and what was the right training for , and he steadily lived up to those ideals.

JAMES HARDIE, M.D. EDIN., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE MANCHESTER ROYAL INFIRMARY, ETC.

James Hardie, who died on March 27th, was born in 1841 [illegible] es from North [illegible] After attending [illegible] he went to the [illegible] e entered the [illegible] Here he came nder the influence of both Syme and Lister, the latter whom had just begun his remarkable work at Edinburgh. nder such surroundings Hardie early became imbued ith an enthusiasm for surgery and possessed with a esire to become a surgeon, but after graduating as M.D. 1862 several years passed before there appeared any ospect of his aspirations being realised. The late sixties" found Dr. Hardie immersed in the exacting work a busy general practice at Harpurhey, in the outskirts Manchester but still bent upon being a surgeon. A newomer in a large town, without influence, wanting even the nglish surgical qualifications so helpful, if not actually sential, for the gaining of a hospital appointment, the ance of his ever becoming a surgeon seemed very remote. ut James Hardie's nature was one not easily depressed. In ite of the trying demands of a large general practice he [illegible] anaged to gain enough reputation [illegible] to the, at that time, small clinical [illegible] l children, now the Manchester orthern Hospital. This success was followed by his election visiting surgeon to the large Manchester Poor-law Town- [illegible] spital appointments Dr. Hardie decided to give up general ractice and embark upon a career as a pure surgeon. Still, or a long time patients were few and success seemed so emote that even he became dispirited and the public health ervice seemed to offer superior attractions. By virtue of his connexion with the Manchester and Salford Sanitary Association he was selected on the short list for one of the newly created sanitary districts of the county of Cheshire and *only narrowly escaped becoming a medical officer of* health. The successful candidate on this occasion was his old fellow-student, Dr. (now Sir) Thomas R. Fraser of Edinburgh, who did him an ever gratefully remembered service by defeating him. After this excursion into public health surgery once more claimed him. By active participation in the medical life of the town, aided by communications to the various medical societies, notably by a paper on the Pathology of Club-foot, Mr. Hardie (as he now began to be c [illegible] aff of the I [illegible] eon. Notwithstanding the fact that he had no previous official connexion with either the institution or the medical school, Mr Hardie succeeded in gaining tl [illegible] fight. To this was soon added t [illegible] district surgeon to the London [illegible] and in 1882, by the retirement o [illegible], Mr. Hardie from assistant surgeon became full surgeon. In this same year he became by examination a Fellow of the Royal College of Surgeons of England. From this time, or rather from the date of his first appointment to the infirmary, his success was assured, but the bare narration of these successive steps in his career affords no idea of the amount of energy and persistent effort required to accomplish it. For a stranger in a general practice in a large town in a few years to gain a footing on the staff of a leading teaching hospital is in itself no small achievement, and argues much ability backed by great force of character. Mr. Hardie's active connexion with the infirmary lasted until 1901, when on reaching the age limit he became consulting surgeon. In 1894 he was elected on the Council of the Royal College of Surgeons of England, and throughout his term of office took an active and prominent part in the affairs of the College.

As a surgeon Mr. Hardie almost from the first became an enthusiastic adherent of Lister, and while remaining a "good all-round man" he early devoted himself especially to the domain of plastic surgery. In this department he became distinguished for the originality, boldness, and ingenuity of his operations and the dexterity and success with which he carried them out. Chief amongst many modifications of existing operations he conceived the idea of transplanting the terminal phalanx of the little finger to form the bridge of the nose in the Tagliacotian operation for the restoration of that organ, a procedure which he carried out with success in many cases. Confident in the safety of strict antiseptic methods, he was the first in this country to perform and to advocate the open method of operating upon Dupuytren's contraction by which the contracted hypertrophied palmar fascia is freely exposed and completely removed. This he did at a time when any interference with the palmar fascia other than by timid tenotomies was dreaded by most surgeons. In the operative treatment of hare-lip and cleft palate he earned a deservedly high reputation; in his hands these operations appeared most simple procedures. Those who watched him operating in many of these cases were always impressed by the simplicity of the methods which he employed. In the most severe cases, rarely, if ever, had he recourse to any of those out of the way plans set forth in surgical literature. Under Hardie's deft hands the most severe deformities were rectified by ordinary simple straightforward methods. Unfortunately, qualities of this nature and cunning of hand cannot be described on paper, and, moreover, Mr. Hardie had a disinclination for writing. He did not often publish his cases or explain his methods, and so scarcely gained that credit to which he was justly entitled.

The various institutions with which he was connected had in him an active officer, one interested in all the details of their management and politics. Coming from Edinburgh, which owes so much of its repute as a medical teaching centre to its extra-mural schools, he was a moving spirit in an attempt to provide Manchester with similar advantages for its students Fortunately or unfortunately, the effort was abortive and ended in failure through the defection of some of its supporters just when success seemed assured, to the lasting regret of at least one of its projectors. The long debated question of the situation of the new infirmary found Mr. Hardie a strong advocate for the rebuilding of a larger hospital on the original *central site. In furtherance of this, and to illustrate* his views upon double wards and the plenum system of ventilation, he had drawn up by his friend the architect of Marischal College, Aberdeen, the plan of a beautiful Gothic building. This, whatever might have been its merits or demerits as a hospital, by its originality of design, beauty, and artistic proportions would have adorned a magnificent site and conferred distinction on the town.

His active, restless temperament made him take a share in all medical affairs; he was for long a leading member of the Edinburgh University Club, the Manchester and Salford Sanitary Association, and other public bodies more or less allied to medicine. As a colleague he was always conspicuous for loyalty to his fellow workers, particularly in reference to any public question. While he might on occasion be tenacious of his individual rights, he was invariably just and reasonable in his attitude towards the claims of others. *Gifted with a capacity for expressing* his views clearly and distinctly, and always having definite opinions, he was a valuable member of any committee. He could make up his mind quickly and definitely upon any matter, fearlessly take a side, and loyally stick to it. There was no suspicion of temporising or wavering in his character, which led to his gaining a well-deserved reputation for honesty of purpose and direct dealing. Unhappily ill-health, which attacked him comparatively early in life, militated against the full development and exercise of his undoubted abilities and *impaired his usefulness.* However, in spite of all he accomplished something, and his older friends who knew him in early days will cherish the memory of what he used to be and of what he did accomplish, while regretting what he might have done with better health. He married early in his career Miss Young, daughter of the well-known Edinburgh surgical instrument maker, who survives him. Their one child, a son, died some years ago.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Theodor von Dunin, physician to the Hospital of the Child Jesus in Warsaw.—Dr. Hermann Julius Thomas, medical councillor, of Badenweiler and Nervi, where he practised during the winter months.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—*At the Second Professional Examination* of the Conjoint Board in Anatomy and Physiology held on April 1st, 2nd, 5th, and 6th, 98 candidates presented themselves, of whom 66 were approved and 32 were rejected. The following are the names of the successful candidates:—

George Aldridge, St. Bartholomew's Hospital; Thomas Stevens Allen, Guy's Hospital; Charles Vernon Anderson, St. Thomas's Hospital; Charles Nelson Atlee, St. Mary's Hospital; Herbert Ferris Barge, Guy's Hospital; William Rawson Barlow, Middlesex Hospital; Tremlett Brewer Batchelor, B.A. Oxon., Oxford University and London Hospital; Ellis Campbell Bowden, London Hospital; Ronald Edgar Russell Burn, St. Bartholomew's Hospital; Terence Campbell Butler, Westminster and King's College Hospitals; Albert James Clarke, St. Bartholomew's Hospital; Thomas Clarke, Leeds University; Charles Frederick Constant, Guy's Hospital; Hugh Gregan Crawford, Guy's Hospital; Joseph Henry Creasy Davis, Middlesex Hospital; Alfred Evan Lewis Devonald, King's College Hospital; William Everard Sherard Digby, Guy's Hospital; John Chute Ellis, New Zealand University and London Hospital; Alfred George Timbrell Fisher, University College, Bristol, and St. Bartholomew's Hospital; Charles Michael Forster, B.A. Cantab., Cambridge University and C [illegible] Green, St. Mary's Hospi [illegible] Caracas University and [illegible] Hadfield, St. Bartholom [illegible] B.A. Cantab., Cambridge [illegible] *Ravensworth Hart,* Guy' [illegible] University; John Rollo [illegible] Howard Heaton, London [illegible] College Hospital; Bernai [illegible] Cross Hospital; William [illegible] Jefferson, Manchester [illegible] Cambr [illegible] Bartholomew's Hospital; [illegible] Noel [illegible] ollege; John Forbes O'Connell, St. M [illegible] George Orchard, St. Bartholomew's [illegible] Bhaibabhai Patel, Bombay University [illegible] *Hospital;* Cresswell Lee Pattison, St. M [illegible] eph Herbert Pearson, London Hospital; George Harold Pearson, London Hospital; John Pinder, Leeds University; Courtenay Henry Gerard Pochin, Guy's Hospital; Thomas William Watkin Powell, St. Mary's Hospital; Richard Cruikshank Poyser, Guy's Hospital; Richard Frith Quinton, London Hospital; Edward Gordon Reeve, Guy's Hospital; Cecil Goodwin Reinhardt, Leeds University; Edmund Uniacke Russell, King's College Hospital; Ahmed Sabri, Cairo Medical School and St *Thomas's Hospital; Wilfrid Ralph* Sadler, St. Bartholomew's Hospital; Henry Kenneth Victor Soltau, St. Bartholomew's Hospital; William Steuart, St. Bartholomew's Hospital; Hugh Stott, University College; William Edward Tanner, Guy's Hospital; Julian Taylor, University College; Keshav Sadashiv Thakur, L.M. & S. Punjab, Punjab University and University College; Victor Vesselovsky, St. Thomas's Hospital; Victor David Collins Wakeford, St. Bartholomew's Hospital; Philip James Watkin, Guy's Hospital; John Robert Douglas Webb, Liverpool University; and Cyril Guy Whorlow, St. Thomas's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery held on March 29th and 30th and April 1st the following gentlemen were approved in the undermentioned subjects:—

Chemistry and Physics.—David Cohen Bernstein, Birmingham University; Gwilym Tremain Davies, Middlesex Hospital; Frederic Hopkinson, Royal Technical Institute, Salford; Montague Fred Hopson, Guy's Hospital; Charles Henry Housden, Battersea Polytechnic; *Hubert Humphry, Birkbeck College;* Bertram Howard Jones, Middlesex Hospital; Michael William Joseph, Birmingham University; Reginald Charles Kershaw, Liverpool Municipal Technical School; John Farnham Mace, Birmingham University; George Matthews, Guy's Hos [illegible] ham University; Herbert [illegible] Cardiff; William Davies Mo [illegible] Bertram Neely, Guy's Hospi [illegible] pital; Harold Robert Parkes [illegible] Pasmore, Royal Albert Mem [illegible] Rhodes, Cambridge Universi [illegible] tute; Gilbert John Stuart [illegible] hool, Canterbury; Oscar Henry Tittman, Charing Cross Hospital; and Charles Henry Wilson, University College, Cardiff.

Chemistry.—Samuel Trude Fripp, Polytechnic Institute; Charles Edward Murch, Birkbeck College; Roy Harry Barkly Pallett, Middlesex Hospital; *Christopher* Hodgson Pywell, Middlesex Hospital; John James Ward, Harris Institute, Preston; and Lewis William Wilson, Charing Cross Hospital.

Physics.—Eric Sutton Dickin, Liverpool University; John Gordon Harris, Royal Technical Institute, Salford; Herbert James Pegler, Guy's Hospital; and Felix Lambert Pradier, Polytechnic Institute.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

PRIMARY EXAMINATION, PART I.

Biology.—J. F. Bourke, Glasgow; P. R. Cross, Birkbeck College; J. E. Kitchen, Manchester; L. F. Pain, Royal Free Hospital; and H. F. Rose, Cambridge.

Chemistry.—J. F. Bourke, Glasgow; P. R. Cross, Birkbeck College; J. E. Kitchen, Manchester; W. A. Oaten, Royal Free Hospital; and H. G. Steel, St. Mary's Hospital.

Materia Medica and Pharmacy.—P. R. Cross, Birkbeck College; *F. I. G. Hunter, Royal Free Hospital and Liverpool;* and R. E. Laurent, Edinburgh.

PRIMARY EXAMINATION, PART II.

Anatomy.—H. Cox, Birmingham; H. N. Eccles, Guy's Hospital; *C. de C. W. Langdon,* Manchester; P. J. Montgomery, Middlesex Hospital; F. G. Norbury, Glasgow; H. Rimington, St. Bartholomew's Hospital; and R. A. Robinson, Liverpool.

Physiology.—H. Cox, Birmingham; L. S. Daly, Manchester; P. J. Montgomery, Middlesex *Hospital;* F. G. Norbury, Glasgow; H. Rimington, St. Bartholomew's Hospital; and R. A. Robinson, Liverpool.

UNIVERSITY OF LIVERPOOL.—The following is a list of the successful candidates in the recent examination for the Diploma in Tropical Medicine:—

R. G. Abercrombie, J. R. P. Allin, H. P. W. Barrow, P. Carr-White, *W. S. Clark, R. Cope, W. D. Hayward, W. P. Meldrum,* J. C. Murphy, M. G. Samuel, M. H. Thornely, and W. S. *Webb.*

UNIVERSITY OF DURHAM.—At the Convocation on April 3rd the *following degrees* were conferred:—

Doctor of Medicine.—Gilbert Iliffe Cumberlegge, Robert Alexander Morris, William Waters Stainthorpe, and Percy Edward Turner.

Degree of Doctor of Medicine for Practitioners of 15 Years' Standing.—Graham Thomas Baylis Blick, Alfred Arthur Hill, Ernest William Gurney Masterman, Edward James Fleetwood Moore, John Percy Oliver, and Walter John Ernely Sumpter.

Master of Surgery (M.S.).—Bryden Glendining.

Bachelor of Medicine (M.B.).—Kenneth *Bruce* Allan, College of Medicine, Newcastle-upon-Tyne; Harriett Amelia Rachael Apps, London School of Medicine for Women; Eldred Curwen Braithwaite, Leonard Foster Browne, and Charles Ernest Lewis Burman, College of Medicine, [illegible] n Evans, Guy's Hospital; Jo [illegible] College, Belfast; Henry Fre [illegible] Duncan Matheson Johnston, St. Bartholomew's Hospital; Annie Viccars Mack, College of Medicine, Newcastle-upon-Tyne; Jessie Margaret Murray, London School of Medicine for Women; *and* Friederike Rahtkens, College of Medicine, Newcastle-upon-Tyne; William Rollin, Robert Henry Smallwood (Rev.), and Theodore William [illegible] -Tyne.

Ba [illegible] of Medi [illegible] Evans, Guy's [illegible] llege, Belfast; [illegible] tle-upon-Tyne; [illegible] ne for Women; [illegible] nry Smallwood [illegible] Stallybrass, College of Medicine, New-

Bachelor of Hygiene (B.Hy.).—Guy Rowland East, John Tyrer Johnson, William Roy Macdonald, Elizabeth Niel Neil, Arthur John Rushton O'Brien, and Gertrude Ethel O'Brien.

Diploma in Public Health (D.P.H.).—Guy Rowland East, John Tyrer Johnson, William Roy Macdonald, Elizabeth Niel Neil, Arthur John Rushton O'Brien, and Gertrude Ethel O'Brien.

UNIVERSITY OF ABERDEEN.—The following degrees in Medicine have been conferred:—

Doc [illegible] —William Angus, Robert Chalmers, [illegible] Cowan, James Alexander Davidson, [illegible] Hugh Skinner.

Master of Surgery (Ch.M.).—James Robertson.

Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—Alexander Greig Anderson, William Anderson, David Main Baillie,

LONDON SCHOOL OF TROPICAL MEDICINE.—The examination in Tropical Medicine held at the end of the twenty-ninth session, January to April, was successfully passed by the following candidates:—

*J. A. Beamish, *I. Davenport Jones, Captain, I.M.S., *G. M. Gray (Colonial Service), *L. Garnin, J. H. McDonald, Major, I.M.S., S. A. Winsor, J. W. Archibald (Colonial Service), Miss Dora Watney, M.B., E. M. Franklin (Colonial Service), D. C. Master, R. Mortimer Johnson, T. Hood Rankin (Colonial Service), C. W. O'Keeffe (Colonial Service), J. C. Spillane, T. F. Lumb (Colonial Service), A. W. Grant (Colonial Service), G. B. Mason (Colonial Service), A. H. Fyzee, and R. C. Thomas.

* Passed with distinction.

It is proposed to hold advanced

i.e., in Protozoology, Arthropod

commencing on or about Jan. 1

each year, for medical men and veterinary surgeons. Students who have attended the ordinary course are eligible, and also others who satisfy the teachers in these subjects that they possess sufficient rudimentary knowledge to benefit by these courses. The advanced course in each subject will begin at the expiration of the ordinary course in that subject at 10 A.M., viz.: General medical zoology, first week of

week of the session; arthro-

session; and helminthology,

angements are so made that the advanced course in all three subjects can be taken during the three months or the whole time may be spent on one subject. Special arrangement may be made with the teachers where it is desired to spend more time on one branch to the exclusion of the others or to undertake research work in that subject. The subjects in each are as follows: The advanced course upon general medical zoology (Colonel A. Alcock, I.M.S.) will consist of eight meetings, at which will be considered the more important morphological and *biological characters of the groups* which are not *treated* in the courses of protozoology and helminthology, such as the rats and mice, the blood-sucking bats, the venomous reptiles and fishes, and certain forms of minor importance, particular attention being directed to the venomous snakes. The lectures will be based upon demonstrations of actual specimens. The advanced course in protozoology (Dr. C. M. Wenyon) will consist of demonstrations and practical work. No formal lectures will be given, but each student will receive individual instruction in the laboratory. The course will be almost entirely a practical one in order that the students may become acquainted with some of the more difficult methods of preparation and culture of the protozoa. The advanced course upon arthropodology (Colonel Alcock) will consist of 12 meetings, at which will be considered: (1) The general morphology of the several constituent classes of the phylum and of the orders diptera, siphonaptera, hemiptera, siphunculata, and acarina; and (2) the generic and specific characters and life-history of those forms which are concerned in parasitism and the *dissemination of disease in man*. The lectures will be based upon *demonstrations* of actual specimens. The advanced course in helminthology (Dr. R. T. Leiper) will consist almost exclusively of practical work in the research laboratory under the supervision of the helminthologist. The structure and development of the more important human helminthes, already considered in the ordinary course, will be restudied in detail. Many of the rarer parasites will also be examined. Considerable attention will be given to methods of collecting and preserving the various kinds of worms, and for this purpose occasional visits will be made to abattoirs. The last two days of the course will be devoted to the study of leeches. Past students of the school who have taken a course of more than one month will be admitted at the rate of £1 1*s.* per week; others at the rate of £1 11*s.* 6*d.* per week. Students who have attended these *courses are eligible for the Cragg's prize* and for the appointments as Cragg's Investigators. Further particulars as to the course of study may be had on application to Dr. C. W. Daniels, the Director at the school, Connaught-road, Albert Dock, E., or to the Secretary at the head office, *Seamen's Hospital, Greenwich, S.E.*

Dr. Franz Ritter von Haberler of Innsbruck has been appointed Ministerial Councillor and Medical Referee to the Austrian Ministry of the Interior in succession to the late Dr. Daimer.

MEDICAL MAGISTRATE.—Among a number of new magistrates whom the Lord Chancellor has just appointed

l Matthews Browne,

Browne has been a

WE are requested to state that forms of application for the admission of children into the Lord Mayor Treloar Cripples' Home and College, Alton, can be obtained from Sir William Treloar, 122, Mansion House Chambers, London, E.C. Special consideration will be given to applications for the admission of children suffering from tuberculous disease of the bones and joints.

LITERARY INTELLIGENCE.—Messrs. Hammond, Hammond, and Co., of 12, *Paternoster-row, have just issued* a new work by Dr. A. D. Edwards, medical officer of schools for Bournemouth, entitled "Children of the Poor." The book deals with such subjects as child-life in the slums, underfed and overworked children, pain and suffering in childhood, *childhood in the* workhouse, *open-air* schools, and the *Children Act* of 1908.

THE MIDLAND MEDICAL UNION AND THE MIDWIVES ACT.—The following resolution was passed at a meeting of the Midland Medical Union held at Chesterfield on April 8th, after a discussion of the position held by the medical practitioner under the Midwives Act, 1902:—

the Public Assistance Authority shall, if requested, issue an order

We are informed by the secretary to the union that the resolution has been forwarded to the Departmental Committee of the Privy Council which is now sitting on the matter.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on March 23rd at Caxton House, Westminster, with Dr. F. H. Champneys in the chair. The Board considered the following charges amongst others against certain midwives and ordered them to be struck off the roll:—

M—— J—— B——, that being in attendance as a midwife at a con-not send for a doctor. R—— K——, S—— J—— L——, and H—— T——, that they were uncleanly and did not take with them to confinements the appliances and antiseptics required by Rule E, 2. E—— M—— B——, for habitual drunkenness. A—— G——, that on March 9th, 1895, she was convicted of having unlawfully and feloniously used an instrument with int creupon sentenced to be kept in that on Oct. 27th, 1904, she proc by the Central Midwives Board by causing to be made and by producing a false and fraudulent certificate of good moral character. S—— A—— M——, that she had been convicted for being drunk and disorderly during the years 1902 to 1904, and that on April 27th, 1905, she procured the grant of a certificate to her by the Central Midwives Board by making a false and fraudulent representation that she was trustworthy, sober, and of good moral character, and by causing to be made and by producing a false and fraudulent certificate to this effect.

The documents relating to the last two cases were ordered to be sent to the Public Prosecutor. The following midwives were cautioned after charges against them had been considered: M. A——, A. M. B——, and F. C——. E. M—— and M. E. S—— were censured after charges alleged against them had been considered.

THE CHILDREN'S FRESH AIR MISSION.—The annual meeting of this charity will be held, under the presidency of the Lord Mayor, at the Mansion House, on April 27th, at 3 P.M. It exists to provide change of air for the children of the poorer classes, especially the sickly ones, in the congested districts of Holborn, Clerkenwell, and St. Luke's, and by arrangement from other parts of London. The objects of the mission should appeal to all who look forward with eagerness to the rest and recuperation which they derive from their own annual holiday, and the committee states that a subscription of 10s. will give a child a fortnight in the country. The mission was founded in 1882, when 269 children were sent out of London, and the numbers steadily progressed until last year 3224 received the benefits of the society, making a grand total of 70,763 since its foundation. It may be fairly claimed that this work has had a beneficial effect upon the health of a helpless section of the community in which the recent report of the Education Committee of the London County Council has proved a sadly great amount of disease to exist. We commend the mission to our readers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Recess.

BOTH Houses of Parliament adjourned on April 7th for the Easter Recess. The House of Commons will reassemble on Monday, April 19th, and the House of Lords on Tuesday, the 20th. Since Parliament met in February a large portion of the time of the Commons has been occupied with financial business, and accordingly the Government programme of legislation is not far advanced for the season of the year. A second reading, however, has been obtained for the Housing and Town Planning Bill. It is not going to be sent to a Standing Committee this year, and it is highly probable that the Government wil take steps to accelerate its rate of progress after the Easter holidays.

The Progress of Private Members' Bills.

Private Members' Bills under the stress of modern legislative conditions have little chance of reaching the Statute Book. Few of them do reach it, but that fact in no way seems to deter Members from introducing measures on their own account to further causes in which they have an interest. Frequently the object is merely to embody definite proposals in a public document in order that a measure of attention should be given to them both in and out of Parliament. About 150 Bills have already been brought in during the present session in the House of Commons. The vast majority of them have not yet received a second reading. Amongst those which have been fortunate to make progress is Mr. BRAMSDON's Oaths Bill which is designed to substitute the taking of an oath by uplifted hand for the prevalent practice of "kissing the book." This measure has passed through its committee stage. Sir WILLIAM COLLINS's Bill dealing with the superannuation of asylum officers has been sent to a Select Committee. Amongst the Bills which are awaiting a second reading are the Asylum Officers' Superannuation (Scotland) Bill, the Coroners' Inquests Bill, the Deaths Registration and Burials Bill, the Infant Life Protection Bill, the Local Education Authorities (Medical Treatment) Bill, the Medical Acts Amendment Bill, the Necessitous Mothers (Assistance) Bill, the Nurses Registration Bill (introduced by Mr. MUNRO FERGUSON), the Nurses Registration (No. 2) Bill (introduced by Mr. FINDLAY), the Prohibition of Vivisection Bill, the Public Health Officers Bill, the Registration of Nurses (Scotland) Bill (introduced by Mr. CLELAND), and the Vivisection (Abolition) Bill.

Beri-Beri on Merchant Ships.

Several questions have recently been addressed in the Commons to the representatives of the Board of Trade in the deaths of Asiatic firemen and seamen on board British ships from beri-beri. The replies have dealt with the each case brought forward, but Mr. TENNANT, the Parlia Secretary to the Board, has several times embodied in his statement to the effect that the cause of beri-beri has not y ascertained, but it is probable that bad or insufficient food m dispose to the disease.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 7TH.

Escapes of Lunatics.

Mr. CHIOZZA MONEY asked the Secretary of State for the Department how many imbeciles and lunatics had escaped from asylums in the United Kingdom during the last five years, a many of the escaped lunatics were recaptured.—Mr. GLA replied: I have not the figures for the United Kingdom, l following are the number of escapes and recaptures resp in the last five years in England and Wales:—

Year.	Escapes.	Recaptures.
1904	367	327
1905	363	328
1906	396	349
1907	356	317
1908	364	303
Total	1846	1623

A Grant to Mr. H. W. Cox.

Mr. BOWERMAN asked the Prime Minister what was the resu consideration given to the case of Mr. H. W. Cox, who recently serious and permanent injuries in connexion with x rays work.—Mr. HOBHOUSE (Secretary to the Treasury, who rep behalf of Mr. ASQUITH) said: A grant has been made to Mr. the Royal Bounty Fund.

Escapes from Asylums.

Mr. CHIOZZA MONEY asked the Secretary of State for the Department, with reference to the 67 imbeciles and lunati escaped from public asylums in England and Wales between and March 31st, 1909, how the 67 lunatics in question were with regard to the degree of their lunacy or imbecility by the ties; how many of the 67 had been recaptured; and what was taking with asylum authorities to protect the public f average of five escapes from public asylums per week.—Mr. G replied: The Commissioners in Lunacy cannot yet furnish mo information referred to in the first part of the question. 57 ou 67 who escaped were recaptured. The Commissioners conside agree, that asylum authorities generally in the country take caution to prevent escapes. As they state in the report wh presented to Parliament last week, public opinion would not the retrograde step of making asylums once more in the n prisons.

Mr. ARNOLD HERBERT asked the Secretary of State for th Department whether, having regard to the number of escap convict prisons and lunatic asylums, and the difficulty and persons who had so escaped, he ith bloodhounds in cases of future ply: I objections to ad e case of I am, however, the subje

Medical Inspection in Irish Schools.

Mr. VINCENT KENNEDY asked the Chief Secretary to th Lieutenant of Ireland whether he was aware that in Ireland th no medical inspection in the schools, although most countries, England, enjoyed it; that in Hungary the schools were inspected three times annually; and that without medical the Prevention of Tuberculosis Act would largely lose its portions of the Children Act (Clause 122) would be inopera Ireland; and further, whether he would see that Ireland would as much benefit from this legislation as England would.—Mr. replied by written answer: I am unable to add anything to th given on my behalf by my right honourable friend the General for Ireland to a question asked by the honourable Mem South Down on Feb. 26th, 1908.

The Drainage of the Village and District of Sketty.

Sir DAVID BRYNMOR JONES asked the President of the Local G ment Board whether the Swansea rural district council applied Board on or about June 1st, 1908, for its sanction to borrow £13 sewerage works for the village and district of Sketty within th of the council, and that an inquiry was held by one of the Inspectors into the question of the expediency of the prop and expenditure in August last; and whether, seeing that the of that village and district was in an unsatisfactory conditi dangerous to the health of the inhabitants, he could see his giving the required sanction at an early date.—Mr. Bu the following written answer: The facts are as stated in the The scheme involves the laying of a sewer on the foreshore below water mark, and to this the consent of the Board of Trade is That department has the matter before it, and as soon as its de has been given I shall be prepared to deal with the applicati sanction to the loan.

The Feeble-minded in Workhouses.

Mr. A. H. SCOTT asked the President of the Local Go Board whether he could issue an order to all Po remove or isolate when possible all feeble-minded epileptics, imbeciles, and lunatics from other inmates of the workhouse recommended in the recent reports of the Royal Commission on law and also in the reports of the Royal Commission on Aged P 1895.—Mr. BURNS (by written answer) replied: To the extent to existing accommodation or additions to accommodation in stitutions may suffice for the modification of present arrangements *fecting the classes to which the question refers the powers of the* ocal Government Board and of the Poor-law authorities could, no [illegible]

Notes, Short Comments, and Answers to Correspondents.

UNQUALIFIED DENTISTRY.

AN action was concluded in the Pontypridd county court on March 21st before his honour Judge Bryn Roberts and a jury. The action was brought by a tramway conductor named O'Brien against an institution trading as the Hygienic Institute of Pontypridd and Glasgow. The plaintiff alleged that the defendant's local manager, who was not a qualified dentist, extracted 12 of his teeth (four of them being sound teeth) very unskilfully, that his gums were much torn, that four days after the extraction they were still bleeding, that they had to be stitched, and that his health was impaired. Medical evidence as to the stitching was given by one of the staff of the Cardiff Infirmary. His honour pointed out that the liability here did not depend upon whether the defendant's servant was or was not qualified. They had held themselves out as competent to do certain work, and if it were not done skilfully they would be liable for the consequences. The jury returned a verdict of £60 for the plaintiff. This case is one more example of the dangers attendant upon unqualified practice. It is undoubtedly true that the mere fact of being qualified does not exempt a man from the consequences of unskilful treatment. But the difference between a qualified and an unqualified man is great, for the qualified man has had a thorough training and the unqualified has not. But there is a certain class of person who thinks nothing of intrusting his body to any adventurer who by the aid of a glib tongue and ingeniously worded advertisements sets out that he can cure various ills, although the same person would never think of intrusting the care of his horse or the management of his affairs to anyone but a trained veterinary surgeon or a trained lawyer. Such a man has only himself to blame if, as in the present case, he comes to grief.

HYPNOTISM: A DISCREDITABLE CIRCULAR.

PROBABLY some of our readers have received a circular signed "F. J. B.," care of Pearson and Sons, Printers, 34, Mark-lane, London, E.C., the writer of which expresses his readiness to teach the practice of hypnotism to medical men who may be prepared to pay for it. Such a circular is before us, from which we learn that the proposed "instruction will be private and a hypnotic subject will be provided to practise upon. Every phase of hypnotism will be explained, and as far as possible demonstrated, *without reserve.*" The anonymous would-be instructor supports his advertisement by recounting a few lightning cures wrought by his practice of hypnotic suggestion, and adds to them the following description of a feat which we can only call hypnotic doping. "The writer hypnotised a man entering for a boxing competition at 'Wonderland.' He had his nose broken, felt no pain, immediately attended the East London Hospital, where they expressed surprise that he should take it so coolly." "F. J. B." urges the utility of hypnotism as a therapeutic agent and after remarking that "the books on the subject are as numerous as they are useless," makes the absurd statement that medical men "know that with many of their patients their words can either kill or cure." Such a circular carries its own reprobation.

WORKHOUSE MEDICAL OFFICER AND POST-MORTEM FEE.

THE question of a medical officer of a workhouse not being allowed a fee for making a post-mortem examination on a workhouse inmate was raised by Mr. R. M. Going, medical officer at the East Preston (West Sussex) workhouse on April 7th. He applied for his fee, but the deputy coroner (Mr. A. W. Rawlinson) held that Mr. Going was not entitled, he being the workhouse medical officer. Mr. Going urged that the fee was allowed to other workhouse medical officers in the county, but the deputy coroner said the county auditor had disallowed such payments, and he (the deputy coroner) was advised that a workhouse doctor was not entitled to the usual post-mortem examination fee. The deputy coroner asked Mr. Going if he could give him any legal authority for the payment, whereupon Mr. Going said he would take steps to secure the necessary authority. There will, we fear, be some difficulty about this, but we have often felt that a medical man should be justly entitled to the usual fee for post-mortem examinations whether holding an official capacity or not.

LEPER ASYLUMS IN INDIA.

Sir J. Muir-Mackenzie, K.C.S.I., Member of Council of the Governor of Bombay, has recently opened a new leper asylum which has been erected by the Scottish United Free Church Mission, aided by a grant from the Government, at Khondia, Burkut, near Poona. Dr. J. Rutter Williamson, who presided on the occasion, said the conception of that new and large asylum originated with one of the secretaries of the Mission for Lepers in India and the East nearly six years ago. The society in question was founded in 1874 for the express purpose of caring for those afflicted and often repulsive members of society who in India and other Eastern countries were *so* numerous that they were often neglected and even starved. Since 1874 the work had steadily grown until now the society had lep asylums and homes, for untainted children of lepers in fewer than 76 places in India and the East, in every one of whi there were European ladies and gentlemen giving their time a thought to the care and treatment of the sufferers. These asylu were scattered over the whole of India from Kashmir on t northernmost frontier to the very south of the peninsula, and also Burma, Siam, Japan, China, Sumatra, Korea, and the Philippi Islands. This new asylum at Khondia had been built to accommod 200 lepers—100 men and 100 women. The society had at present un its care, in its various institutions, 8206 lepers and 613 untaint children. Though those figures seemed large they bore a very sm proportion to the total number of lepers in India, which was estima at about 400,000. Sir J. Muir-Mackenzie, in the course of address, observed that the necessity of establishing leper asylu had long been recognised by the Government, who had been preven from doing more only by the want of funds. The Government w well aware of the danger to which the public were exposed by unfettered wandering of lepers through the large centres of pop tion. To some extent they were provided with an instrument dealing with this danger in the Lepers Act, which enable magistrate in any area to which the Act had been applied to com an indigent or begging leper to an asylum. The Act, however, practically remained a dead letter, owing to the inadequate suppl asylums. This new building would help to remedy the evil so fa the district of Poona was concerned.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to *the Agent to whom the subscription is paid, and not to* THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED *TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.* It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address

ON

MOVEABLE KIDNEY, WITH DETAILS OF AN OPERATION FOR FIXING THE KIDNEY.

Delivered at the Annual Meeting of the Ipswich Clinical Society on Feb. 10th, 1909,

BY SIR W. WATSON CHEYNE, BART., C.B., F.R.S., F.R.C.S. ENG.,

SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, ETC

GENTLEMEN,—The surgical treatment of moveable kidney is a question which has given rise to great diversity of opinion, the chief objection urged against the operation of nephropexy being that it often fails to remove the symptoms from which the patient has been suffering. Indeed, not infrequently the patient after a few months is as bad as, or worse than, before the operation. There is more than one explanation of this result. In the first place, the cases may have been unsuitable for operation—that is to say, the loose kidney has not been the whole or even the main cause of the trouble; in the second place, the operation may not have been satisfactorily performed and the kidney may not have been fixed in the proper position; and in the third place, the kidney may subsequently have become loose. Before going on to the consideration of these points let me first refer shortly to the conditions under which mobility of the kidney occurs, to the effect of this mobility on the kidney itself, and to the symptoms to which it may give rise.

In connexion with the occurrence of moveable kidney, I may point out in the first place that it is far more common in women than in men. Various estimates have been given by different authors from which it appears that on an average one case of moveable kidney is met with in about every 200 males, while in females there is one in every 22. It has also been said that it is more common in working women than in those of the better class, but this is not very clear. Nor is there much difference as regards its occurrence in married and single women respectively. In connexion with this difference in sex we have to bear in mind in the first place the greater narrowness of the lower part of the female thorax, and in the second place the arrangement of the clothing. It is very probable that the latter is the main cause of moveable kidney in the female. It is also a striking fact that moveable kidney occurs far more frequently on the right side than on the left side, something over 80 per cent. of the cases affecting the right kidney alone. This is probably in the main due to the fact that the left kidney is more efficiently fixed than the right, partly owing to the more complete development of the perirenal fascia, and partly owing to the shorter length of the renal vessels. We have to remember also that on the right side the right lobe of the liver occupies a large portion of the hypochondrium. Further, moveable kidney seems to be somewhat uncommon under 20 years of age It is most frequently met with in patients between 20 and 50 years of age, after which comparatively few cases are seen. It is said by some that moveable kidney is not infrequent in young children, but I cannot say that in my own experience I have come across many cases of real pathological mobility of the kidney, such a degree of mobility, for example, as to allow one to interpose a finger between the organ and the ribs. One may no doubt sometimes feel the lower pole of the kidney when the child breathes deeply. The majority of the cases of moveable kidney in children seem to be associated with the condition of cyclic albuminuria.

Coming now to the conditions which give rise to moveable kidney, a great variety of suggestions have been made. Thus it is not uncommon to attribute the mobility of the kidney to the disappearance of fat from the fatty capsule. It is held by some that the fat surrounding the kidney is an important element in keeping the organ in its place, but it is difficult to believe that semi-fluid fat can have much influence in this respect. Besides, in the real moveable kidney, the range of movement is far beyond the extent of the fatty capsule. And also in wasting diseases and under many conditions in which fat is lost, there is no evidence that there is an increased proportion of moveable kidneys. It is true that in cases of wandering kidney there is often a marked diminution in the amount of fat surrounding the organ, but this seems to be a sequel of the mobility rather than the cause of that condition. And in post-mortem examinations of patients with [illegible] been found that the fatty caps[illegible] satisfactorily developed, and of [illegible] amount, even though the patient be emaciated. Hence the treatment which is so often pursued of putting patients to bed and trying to increase their fat does not seem a very satisfactory plan. Flaccidity of the abdominal wall has also been mentioned, but although that may be an important point in connexion with the troubles which a wandering kidney may produce it is difficult to believe that it is an inciting cause of the trouble, and the fact that the condition is not more frequent in women who have borne children than in others is distinctly against this view. It has also been stated that increase in the size and weight of the organ tends to make it moveable. It may, no doubt, be to some extent true that in the development of a moveable kidney increased weight of the organ may help, but there is no evidence in support of the view that it is an inciting cause.

None of the foregoing explanations can be looked on as sufficiently satisfactory and we are left with two main views: one that mobility of the kidney is, in part at least, a congenital defect and the other that it is due to mechanical causes.

As regards the first point, it is important to remember that moveable kidney is often associated with the condition described by Glénard, and known as enteroptosis or Glénard's disease. In these cases it is part of the general looseness of the abdominal contents and is developed under the same conditions.[1] The degree of enteroptosis present varies much, and even a comparatively slight amount may cause much discomfort. The conditions which lead to the development of Glénard's disease point to a certain extent to a congenital defect, and I cannot but think that in some cases the groundwork of the mobility of the kidney is also of congenital origin. However that may be, I have no doubt that the development of the pathological mobility of the organ is in the main due to mechanical causes which come into play especially during young adult life.

Mechanical causes may be divided into two sets—namely, those which are acute and sudden, and those which act slowly and gradually. As regards the acute conditions, sudden dislocation of the kidney from various causes, such as a fall from a height or rapid bending of the body, are often spoken of. Violent coughing has also been mentioned as a cause, but patients subject to bronchitis do not seem to be specially troubled with mobility of the kidney. A blow in the lumbar region has been said to produce it, and also violent squeezing together of the lower part of the thorax or violent dragging of the abdominal muscles. None of these causes are, however, very definite, and there are very few cases on record in which there has been undoubtedly a sudden dislocation of the kidney. I fancy that in some of these cases, at any rate where we have a history of the sudden development of symptoms which have led to the discovery of a moveable kidney, the kidney has been moveable beforehand without causing symptoms, and that the injury to which the mobility is attributed has bruised the kidney against the ribs, &c., and thus attracted attention to the condition. It is difficult to believe that the ordinary moveable kidney is of sudden occurrence, because we have to account for the abnormal length of the pedicle and of the various fibrous attachments, which, if not congenital, must have taken a considerable time to develop.

Probably the most important causes of moveable kidney are those which act slowly, and of these the chief is no doubt the arrangement of the dress in the female. Two points are of importance in this respect, namely: in the first place the injudicious use of corsets, and in the second place, the way in which the clothing is supported by means of bands tied round the waist. No doubt in cases where real tight-lacing is indulged in the lower ribs tend to be flattened and thus the abdominal contents are driven towards the lower part of the abdomen. But where no such tight-lacing is employed the wearing of corsets is rather a protection than otherwise. Without corsets, or with very yielding ones, the bands which keep up the clothing tend to drag down the contents of the abdomen and are undoubtedly a potent cause of Glénard's disease. And when we consider the intimate connexion of the various abdominal organs with one another we can hardly have important organs like the intestines, especially the large intestines, dragging down without pulling on the kidney. This tendency is aggravated in the case of fashionable women by wearing high-heeled shoes, the result being that in walking lordosis of the lumbar spine is produced, the antero-posterior capacity of the abdomen is decreased, and the kidneys are projected from under the protection of the ribs. The result is that the bands tied round the waist act still more markedly in the way of depressing the abdominal organs. Once the kidney has become somewhat loose and passed to some extent from under the protection of the ribs it becomes exposed to injury from these constricting bands, and if they are applied towards the upper part of the organ the kidney is constantly pulled down by the weight of the clothes. The peristalsis of the intestinal coils, especially of the ascending colon, will also pull on the pedicle, and under these circumstances the increased weight of the organ itself will also tell, especially where the abdominal walls are lax. In this way a loose kidney may become transformed into a floating kidney.

---

[1] THE LANCET, April 7th, 1906, p. 947.

On examining the condition of moveable kidney, either during an operation or post mortem, it will be found in the early stage that the mobility is limited to the post-peritoneal region, the organ moving upwards and downwards behind the peritoneum. As the case advances, the kidney may project the peritoneum forward, the posterior surface of which may thus form a pocket in which the organ lies, and the vessels and other structures in the pedicle become gradually stretched and elongated. Further, the kidney tends to become rotated, the lower end coming nearer the middle line than normal, thus pressing on the ureter and interfering with the free outflow of urine. This is most marked when the mobility is not great. As the kidney becomes looser the trouble arising from this cause diminishes.

Coming now to the second point—namely, the effect of this mobility on the kidney—we may say that in the majority of cases the substance of the organ does not undergo any marked alteration. Not infrequently, however, the wandering organ becomes small and atrophic, while on the other side compensatory hypertrophy takes place. In some cases there is dilatation of the pelvis of the kidney, in fact a hydronephrosis, which may be accompanied with kinking or twisting of the ureter, and gives rise to the condition known as intermittent hydronephrosis. We may also find in wandering kidneys a condition of chronic nephritis, along with fatty degeneration of the epithelium. In the later stages the kidney may become adherent to structures in the neighbourhood. Trouble of the gall-bladder such as gall-stones is also not infrequent. The stomach is at times markedly dilated and may either be in its normal position or the pylorus may be dragged downwards. The duodenum and the colon may also be dilated, and it is not uncommon to find a condition of general enteroptosis.

In the third place, I may refer shortly to the symptoms to which this condition may give rise. Very often they are indefinite, such as giddiness, faintness, tiredness, and sometimes also anæmia and palpitation. The patients are frequently hypochondriac, neurasthenic, and hysterical, and, according to Suckling, moveable kidney may lead to insanity. Neuralgic symptoms are not uncommon and there is frequently dull pain in the loin, which diminishes when the patient is recumbent but becomes more marked when she is in the upright position, and especially when lifting heavy weights. From the loins the pain spreads in various directions, while on the other hand one may find anæsthetic areas. A second group of symptoms are due to the involvement of the intestinal tract. As regards the stomach, the patients complain of a feeling of weight and fulness, loss of appetite, frequent eructation, and sometimes troublesome vomiting. These symptoms are partly reflex, and may indeed be produced by pressure on the lower pole, even in a kidney which has been fixed. Dilatation of the stomach is also not uncommon and has been explained by actual pressure of the kidney on the first part of the duodenum. But this is not likely, because when in a recumbent position the kid falls outwards. Jaundice may also occur from movea kidney, as the result of pressing or dragging on the com duct, as it comes in contact with the duodenum. Usu there is a tendency to constipation.

Various symptoms may also arise from twisting obstruction of the pedicle. The patient may be seized sudden pain, hæmaturia, small pulse, shock, rigors, &c. symptoms not unlike strangulated hernia or renal calc may occur. This condition may last for 24 hours and gradually subside. The kidney is enlarged and tender, urine increases in amount as the symptoms subside, and tains albumin and numerous white corpuscles. Th symptoms are due to kinking or twisting of the vessel the pedicle, leading to rapidly increasing swelling, pain, tension of the capsule, diminution of the secret and admixture of blood with the urine. In other cases the ureter which is kinked, leading to attacks of intermitt hydronephrosis.

Coming now to the treatment of these conditions, we two lines of treatment—one operative and the other operative. As regards the latter, the treatment cons essentially in attending to the general health and condi and relieving, as far as possible, any of the symptoms w may be present. In addition to that, attempts are to fix the kidney, either by increasing the fat of the pati a plan which seems to be quite futile and not in accord with the pathology of the disease, or by the applicatio various forms of apparatus, with the view of preventing kidney from dropping. The latter consist of belts pads or springs, so arranged as to press on the abdo below the level of the kidney, the hope being that in way the kidney will be prevented from descending. I however, but rarely, especially with a strongly devel abdominal wall, that these pads fulfil their purpose. T efficient they must be applied while the patient is the recumbent position, but as soon as she begins to ass the erect position the muscles lift up the pad and kidney is apt to escape, and either lies under the pa which case it becomes subject to injurious pressure, or below the pad, which then prevents it from returning the loin. The best form of apparatus is, in my experie specially constructed corsets, such as those used in the t ment of Glénard's disease, which keep up the whole tents of the abdomen. They may be reinforced by an pad in the right iliac fossa and are put on in the recum position.

The failure of these various attempts has led surgeon consider the possibility of fixing the kidney in its nor position by means of operation, but, as I hinted at beginning of this lecture, such attempts meet with consi able opposition, because they very often fail to attain t purpose. The first cause of failure is want of selectio suitable cases. In this condition one must be very car in choosing suitable cases for operation, because the kid is often not the sole, or indeed the chief, cause of patient's troubles, and also the condition is frequently as ciated with a large amount of neurasthenia.

As regards the cases which require operation, we may at once that cases where harm is being done—for exam where the pedicle frequently becomes kinked, or where condition of intermittent hydronephrosis has set in, where there is injurious pressure on the duodenum common bile duct—must be treated by operation. again, certain cases are suitable for operation where symptoms are less severe and where they mainly consi pain in the back when the patient is in the upright posit provided they are not associated with general enteroptosis.

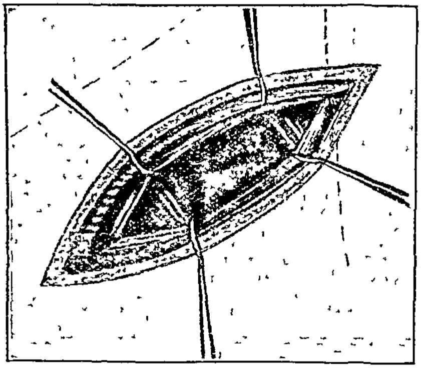
There are two classes of cases, on the other hand, in wh the question of operation is, to say the least, doubtful. the first place, moveable kidney is not infrequently associa with a greater or less degree of enteroptosis. Where th marked the fixation of the kidney is not likely to prod much, if any, benefit unless it is accompanied or followed some attempt to raise the other organs which have a dropped, and that means extensive operations, the succes which is by no means certain. Hence, in such cases it see the most prudent course to see what amount of benefit can obtained by properly constructed and fitted corsets and p before considering the question of operation.

The other set of cases in which operation is of v doubtful benefit is where the condition is accompanied w marked neurasthenia. The general experience is that in these cases not only may no benefit result but the state of the patient may be rendered worse. I have certainly come across a good many cases, especially in hospital practice, where this is the case. At the same time, it must be pointed out that in all these cases the operation has been done from behind, and, as I shall presently mention, it is by no means easy to fix the kidney in its proper position by that method. In contrast to this view, which is the one commonly accepted, there are some who hold that the presence of neurasthenia is, in fact, an indication for operation, and one of the strongest advocates of that view is Dr. C. W. Suckling of Birmingham. Indeed, Dr. Suckling goes further, and looks on moveable kidney as a potent cause of some forms of insanity, and he publishes a series of cases in which the mental condition has improved after the kidney has been properly fixed. In connexion with his statements the operation to which he refers is Goelet's, in which, no doubt, a more accurate position is obtained than by the ordinary posterior method. It is possible, therefore, that this question of operation in marked neurasthenic cases may have to be revised in future. However that may be, the view taken by many physicians that the operation of nephropexy is not a proper procedure, and that the only treatment for moveable kidney is general treatment, such as rest cures, &c., combined with support by belts and pads, is much too extreme There is no question that a considerable proportion of cases are immensely improved by the operation when it is properly performed and when the organ is fixed in its normal position and relieved from pressure by bands, clothing, &c.

Another reason for want of success of the operation of nephropexy is the fact that the kidney may again become loose and there is no doubt that in the earlier operations this did occur not infrequently, especially where the kidney was not brought into actual contact with the fascia on the posterior wall of the abdomen. Since, however, care has been taken in this direction, and especially where the capsule of the kidney is detached on the posterior surface of the organ, the probability of its becoming loose again is very much less

The third point, and the one to which I wish especially to draw attention to-night, is the importance of fixing the kidney, as far as possible, in its normal position, and thus avoiding outside pressure and kinking of the ureter or pedicle. The usual method of performing the operation is by means of a lumbar incision, but I have for some time been dissatisfied with this procedure, chiefly because I have found it very difficult to get the kidney into its normal position. The tendency is to fix it too low down and too far away from the spine, and I have therefore devised an operation which I think enables one to fix the organ in its proper position and which, so far, has given very excellent results.

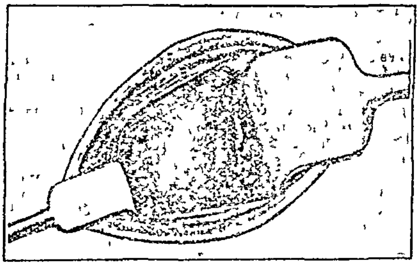
FIG. 1.



Incision down to transversalis fascia. External oblique divided and internal oblique and transversalis muscles retracted

[illegible]ails of this operation. The [illegible] a small pillow under the loin, [illegible]: it is not necessary to push the lumbar region very far forward. An incision is then made along the edge of the ribs and an inch below them, beginning about the edge of the latissimus dorsi, or practically just where, looking down on the patient, the anterior surface of the abdomen ends, and from this point it is carried forwards parallel to the edge of the ribs for from 3 to 4 inches. It is well to make the incision short in the first instance and it can be subsequently lengthened if necessary. The skin and fascia are then divided and also the external oblique muscle; the internal oblique and transversalis muscles can be partly separated and partly divided. They only require a little division here and there, and any nerves that are crossing can, as a rule, be pulled out of the way. One then comes down on the transversalis fascia (see Fig. 1) The fascia is not divided but is pushed towards the middle line, the peritoneum, fascia, and kidney being thus carried forward together. In this way there is less risk of tearing the peritoneum, and we also get at once to the posterior surface of the kidney, which can be easily felt. The edges of the wound being well retracted and the fascia and peritoneum being held well towards the middle line, and the kidney being fixed by the assistant's hand placed in front of the abdomen, the outline of the kidney can be readily palpated. A hole is now made in the perirenal fascia over the posterior part of the kidney, and the renal fat will at once protrude. This hole can now be enlarged vertically over the posterior surface of the kidney, and the fat being pushed outwards or removed the posterior surface of the kidney is exposed. The renal fat is then partly removed and partly pulled forwards with the perirenal fascia (Fig 2), and the kidney is gradually shelled out and can be readily brought out of the wound. The posterior part of the wound is then thoroughly cleared from fat till the diaphragm, the psoas, and the quadratus lumborum muscles are fully exposed. The fatty capsule and the posterior part of the renal capsule are thoroughly turned aside, and I think it is well to take away a good deal of the fat in case it should get in between the kidney and the muscles and prevent firm adhesion. The kidney is then turned forwards and incisions are made through the capsule on the posterior surface, as shown in the diagram (Fig. 3)—namely, a vertical incision running upwards near the inner side of the posterior surface and curving outwards at the upper part towards the upper and inner part of the posterior surface, and then a transverse incision running across the kidney at the lower end of this vertical incision. The capsule can then be stripped off as far as the convex border of the kidney. From each end of the lower transverse incision a small vertical incision is made through the capsule, and then this portion can be pulled down so as to hang downwards from the lower pole of the kidney (Fig. 4). The fatty capsule and loose fascia being prevented from getting in between the kidney and the posterior muscles, the kidney can now be turned back and placed exactly in the position which is desired; it can be put up as far as one wishes, and also at the proper distance from the spine. By means of strong catgut or silk

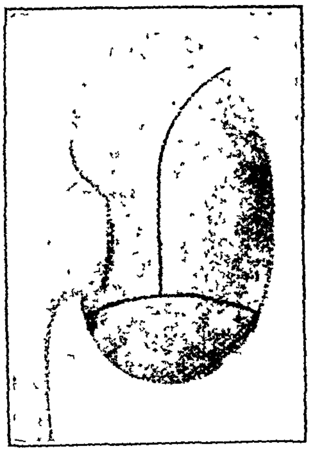
FIG 2.



Perirenal capsule pulled forwards and kidney exposed. About one-half size.

stitches the vertical piece of capsule is now stitched down to the muscles behind, taking care not to stitch it too tightly, because the natural tendency of the kidney is for the outer border not to be so closely in contact with the posterior wall of the abdomen as the inner border is. The piece of capsule which is hanging down from the lower pole is then stitched to the muscles below the kidney, and in this way the raw surface of the kidney is kept in contact with the surface of the muscles behind and acquires firm adhesion to them. The capsule at the lower part is strengthened by stitching down the detached portion of the renal capsule so as to form a sort of ledge on which the kidney rests. The kidney having been fixed, the peritoneum is then allowed to fall back into position and a few stitches will generally bring the deeper muscles together, while the external oblique is closely united by two or three mattress sutures and subsequently by a continuous catgut suture.

FIG. 3.



Incision in kidney capsule on posterior surface of the organ. Rather under one-half size.

Apart from the ease with which one can fix the kidney in its proper position by this operation, there is another great advantage in this incision. Everyone is familiar in cases of moveable kidney with the difficulty of being certain that all the symptoms are entirely due to that mobility, and that other important conditions are not also present, and may indeed be the main cause of the patient's trouble. The four chief things which have to be considered in such cases are: gall-stones, duodenal ulcer, moveable liver and enteroptosis, and appendix trouble, and it is not always easy to say whether the symptoms are due to moveable kidney or to one or other of these conditions.

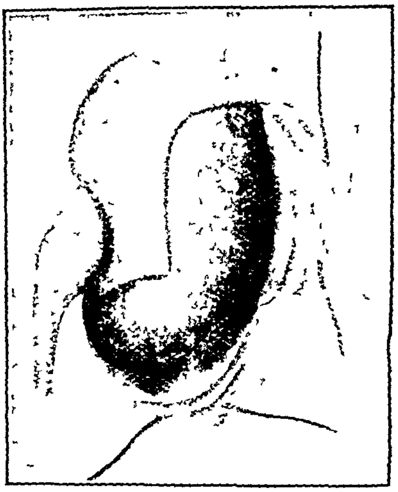
Now, with the ordinary lumbar incision one cannot as a rule make any investigation of the condition of these other parts, but with the incision which I have described it is quite easy to do so. By making an incision into the peritoneal cavity after having exposed the kidney, one can ascertain the condition of the various parts to which I have referred. A moveable liver, of course, is evident at once, even before the peritoneum is opened, and by extending the incision another inch or so forwards one can ascertain the condition of the gall-bladder and of the duodenum. In many of these cases also the colon is so moveable that one can pull up the cæcum and examine the condition of the appendix, or at any rate in trying to do so can ascertain whether adhesions are present or not, which are binding the cæcum down. And not only can these conditions be diagnosed, but some of them can also be remedied without making a further incision. For example, it is, of course, quite easy to stitch the liver up to the edge of the ribs so as to obtain adhesion between that organ and the diaphragm. And also, as in most of the cases of enteroptosis the hepatic flexure of the colon is practically non-existent, the colon can be fixed up to the under surface of the liver at the same time. And then the various conditions in connexion with the gall-bladder are quite accessible by extending the incision somewhat forwards.

As regards the duodenum, of course if it is necessary to do an anastomosis a separate incision will be required, but in all probability that would be left to another day, and in the meantime the exact state of matters has been made out. Similarly with regard to the appendix, if it is bound down by adhesions in the iliac fossa a separate incision will be advisable, and that can be done at the same time and before the upper opening in the peritoneum has been closed, so that one has the advantage of a double access to the appendix.

I have now performed this operation in a good many cases, and the more I do it the more I am satisfied with the results One leaves the operation with the feeling that the kidney has been put in the proper position, whereas I have always been doubtful when the operation was done by the posterior incision. Where, however, we have the condition of intermittent hydronephrosis present and have to perform some plastic operation on the ureter,[2] I think that the old oblique posterior incision is more useful; one gets a more direct access to the pelvis of the kidney by it than by the incision which I am recommending. But these cases are not very common and the condition is usually diagnosed before proceeding to the operation.

This operation was devised some time ago, but I see that in THE LANCET of August 3rd, 1907, p. 283, Mr. E. Stanmore Bishop has described an incision which is practically the same as in the above operation. The further steps of the operation are, however, quite different. Mr. Bishop cuts directly into the peritoneal cavity and carries out the remaining steps of the operation from that cavity. He divides the peritoneum transversely over the lower pole of the kidney and strips down the capsule from the front of the organ. Further, he does not make a point of clearing the fat, &c., from the posterior surface of the kidney. So that, except in the matter of the incision, the two procedures are quite different.

FIG. 4.



Capsule stripped from kidney. Rather under one-half size

---

[2] THE LANCET, July 6th, 1907, p. 11.

NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.—The Lord Mayor will preside at a meeting on behalf of the National League for Physical Education and Improvement at the Mansion House, at 4 P.M., on Wednesday, April 28th. The Bishop of Ripon, Lord Ashbourne, and Lord Halsbury will also address the meeting, and there will probably be other distinguished speakers. The meeting is to call attention to the work of the League and to emphasise the necessity for improving the physical welfare of the nation, whether for purposes of defence or of commercial prosperity. Application for tickets should be made to the secretary of the League, 11, Southampton-row, London, W.C.

Lumleian Lectures

RHEUMATIC FEVER AND VALVULAR DISEASE.

Delivered before the Royal College of Physicians of London on March 23rd, 25th, and 30th, 1909,

BY NORMAN MOORE, M.D CANTAB.,
F.R.C.P. LOND.,
SENIOR CENSOR OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.

Delivered on March 23rd.

THE CLINICAL ASPECT OF RHEUMATIC FEVER.

MR. PRESIDENT, CENSORS, AND FELLOWS OF THE COLLEGE,—The learned person after whom the lectureship is named, to which you have been pleased to appoint me, inherited his estate from a grandfather who fought at Flodden Field. He was himself educated at Queen's College, Cambridge, where he entered in May, 1549, and he retained a taste for learning throughout a long life, in which, as Lord Lumley, he took an active part in the dangerous politics of the time. His wife, a daughter of the twelfth

belonged to Lord and Lady Lumley are evidence of their learned tastes, and were purchased at our benefactor's death for Henry, Prince of Wales. They are preserved in the Royal Library in the British Museum.

It seemed proper in expressing my own gratitude to the

of this lecture-

or achievements

lest you should feel as did King James I. on April 13th, 1603, when the Dean of Durham at Lumley Castle addressed him so elaborately on the history of the family that he grew tired and called out, "Oh! man; gang na further; let me digest the knowledge I have gained, for I did na ken Adam's name was Lumley."[1]

Rheumatic fever, on which I propose to lecture, is so common a disease that every physician has seen very many examples of it, yet its natural history is still obscure in several directions. Its name takes us back to a pathology long anterior to the revival of learning, and acute rheumatism, the commonest synonym for that name, indicates a pathological confusion not wholly dispelled from the medical thought of our own day. How little consideration had been given to the subject for many centuries is shown by the fact that the Aphorisms of Boerhaave, the elaborate summary of the whole medical teaching of the greatest medical teacher of his time, which were printed at Leyden in 1709, do not mention any of the numerous conditions to which the term "rheumatism" has been applied. Boerhaave was professor at Leyden, a city where the frequent chimes seem perpetually to remind one of the heroic conduct of its citizens in the defence of their liberties and of their noble choice of a University as the reward of their valour. His lucid teaching, his unremitting study, his vast learning, his delightful conversation, and his universal kindness made him the object of the respect and the admiration of many generations of students from every part of Europe. One of these, Gerard van Swieten, whom religious intolerance drove from Leyden to Vienna, where he became the most distinguished physician in the empire of Maria Teresa, published a famous commentary on the Aphorisms of Boerhaave which began to appear in 1741, and is to this day the best book for any man to read who desires to ascertain the state of the knowledge of medicine in the middle of the eighteenth century. Van Swieten, in the commentary on the 1490th Aphorism of his teacher—"There is a disease allied to the arthritis, gout and scurvy, which is very common, and is called the Rheumatism"—relates that this subject was first treated in the third edition of the Aphorisms, published in 1722. It "was now mentioned because Boerhaave had himself that year suffered excruciating tortures from this disorder. ...... As long as he had the care of the botanical garden he was constantly there before sunrise; not only in the summer but in the spring and autumn seasons, that he might prepare everything ready for his academic lecture, which he read at 7 o'clock in the morning. I well remember that in the year 1721 he suffered rheumatic pains in his scapula and neck, which were exceedingly troublesome, as in one of the hottest summers he gave advice to a vast concourse of people, in a very cold part of the house in which he lived, not so warmly clad as was requisite: but in a short time after the disorder gave way; but the following year it returned with the greatest violence. ...... When he was well and spoke before his scholars concerning the Rheumatism, about the end of June in the following year, he said for near three months he had endured the most excruciating tortures and at length was so relaxed, that no motion, and scarce any sensation, remained in his lower limbs. He added that, as soon as the pain remitted, he began to run over in his mind all the authors, both ancient and modern, that he had read; for the attention to his own pains excited him: but at the same time he remarked, he had not found anything of consequence in any, excepting Sydenham. ... .. Under this name (Rheumatism) he every year described to his pupils the malady he suffered." Thus the malady of Boerhaave, whatever may have been its true pathological species, was the cause of the introduction of a chapter on rheumatism into every subsequent general treatise on medicine.

Sydenham's remarks on rheumatism prove that he had recognised rheumatic fever, and he is, I believe, the first physician who did so and deserves to be regarded as the discoverer of the disease, though parts of his account show that, like all subsequent writers on the subject, he did not precisely define it nor always distinguish its pains from others of different origin. His description of the symptoms is clear and nothing of the kind is to be found in any earlier writer. He says: "It begins with shivering and shaking and presently heat, restlessness, and thirst, and other symptoms follow, which accompany a fever. After a day or two, and sometimes sooner, the patient is troubled with a violent pain, sometimes in this, sometimes in that joint, in the wrists and shoulders, but most commonly in the knees: it now and then changes place and seizes elsewhere, leaving some redness and swelling in the part it last possessed. At first for some days the fever and the symptoms above mentioned happen sometimes together; but the fever goes off by degrees, the pains remaining, and sometimes rage violently. . ... It may be asked why medical authors have not touched upon it, unless it be supposed this is a new disease. However it be, it is frequent enough now, and though it seldom kills anyone when the fever is off, yet upon the account of the violence of the pain, and the continuance of it, it is not contemptible." Another sentence of Sydenham—"When this disease is not accompanied with a fever, it is often taken for the gout, though it differs essentially from that, as plainly appears to anyone that well considers both these diseases"—probably suggested the writing of a classical passage in the "Commentaries on Diseases," published in 1802, of the Dr. William Heberden whose portrait in extreme age is in our Censors' room. Heberden, in this passage, gives the distinguishing characteristics of gout and then says: "These appear to me to be *the marks of the genuine gout, in almost every one of which* it differs from what I would call the rheumatism. For this does not begin in the foot preferably to any other part, and it seldom continues long in the same place, but will be perpetually wandering over the whole body, even during the first fit, which *has been known to last for* several months. Rheumatic pains will come on suddenly and without any preparatory symptoms. In rheumatisms the chief pain arises

[illegible] which while at rest gives for

of lassitude, than of

of the skin if there be any is not a deep red but rather a *faint* blush. *A severe* fit of the rheumatism often happens without ever returning throughout a very long life, and hardly ever makes periodical returns like the gout. Rheumatic pains very rarely desert the muscles and joints *to seize upon the vital parts.* Very young children will labour under violent rheumatisms; and particularly those who have in them by inheritance the seeds of a gout, with which they are to be afflicted when they arrive at manhood. These are according to my judgement the principal characters of the two distempers; but it must be owned that there are cases, in which the criteria of both are so blended together, that it is not easy to determine whether the pains be gout or rheumatism."

---

[1] Stow's Chronicle

That children are attacked by acute rheumatism is almost the only addition made to the description of Sydenham by the observant Heberden, while his general definition of the disease is less precise than that of Sydenham. It was certainly this admirably drawn contrast of Heberden's which suggested a similar passage in the writings of Sir Thomas Watson, whose medical knowledge and pleasant style caused his book to be widely read and often republished: "In gout the small joints are first and chiefly affected, especially the joint of the great toe; in rheumatism the large. The redness of the gouty inflammation is more bright and vivid than that of the rheumatic; and the fluctuations between agony and ease [illegible] frequent. Gout usually affects one [illegible] iatism usually several at once. The [illegible] ended with turgid veins and with more œdema than in Rheumatism; and is followed, in the majority of instances, by desquamation and itching, phenomena which we do not notice at the close of rheumatic inflammation. Gout is not attended with those drenching acid sweats which are so characteristic of acute fibrous rheumatism. The gout is decidedly hereditary: rheumatism though probably hereditary too is much less distinctly so. The gout occurs rarely or never, whereas rheumatism is not very uncommon before the age of puberty. In gout though many functions suffer, and especially the digestive functions, there is no tendency to carditis: in rheumatism with far less general disturbance, but more fever, that tendency is very well marked. Gout is often, rheumatism is never, associated with chalk stones."

These connected passages from the writings of the three great English masters of medical description—Sydenham, who wrote in the time of Dryden; Heberden, who was a contemporary of Johnson; and Watson, whose last entrance to our Comitia, when the whole College stood up to show him respect, I can remember—all contain confusions from which the expressions of more modern physicians are not wholly free. Sydenham's account, at first clear and admirably describing rheumatic fever, goes on to associate it with quite different conditions, as he also does in his account of the case of the apothecary Malthus in his Epistle to Dr. Brady on the Epidemical Diseases from the year 1675 to the year 1680. Heberden's clinical distinctions show that what Sydenham thought might perhaps be a new disease had not at the end of another century become perfectly familiar to physicians. Watson alone mentions the "tendency to carditis" which had first been observed by Dr. David Pitcairn, who taught at St. Bartholomew's Hospital, to which he was physician from 1780 to 1793, that valvular disease was a frequent result of rheumatic fever.

The history of the attainment of exact knowledge about each particular disease is generally that some prominent symptom has first been noticed and has long been assumed to be the whole disease, and that progressive observation has gradually demonstrated that this prominent symptom may be a result of several distinct morbid conditions. Thus the single disease of past generations of medical authorities comes to be divided into a number of diseases. These for a time continue to be spoken of as if they were related conditions, and finally the partial relation of some and the absolute distinctness of others come to be recognised. The wide meaning of the original term is forgotten and it is applied in some different way or less often falls into disuse. It is easy, for example, to recognise in old writers under the heading "Asthma" cases of some forms of tuberculosis of the lungs, of emphysema, of fibrinous bronchitis, and of laryngismus stridulus, and under that of "Diabetes" of chronic interstitial nephritis as well as of the group of pathological conditions now included under that general designation. The term "rheumatism" is at present undergoing this process. "And rheumatism I send to rack the joints" is a line of Dryden quoted by Johnson in his dictionary, and shows the general sense attached to the term since the poet's time. Physicians were very little more particular and were content to say with Heberden: "The rheumatism is a common name for many aches and pains, which have yet got no peculiar appellation though owing to very different causes." From this general statemer terms "chronic rheumatism" and "acute rheuma became fixed in use, and this terminology, add certain misunderstood phenomena, led to the vie prevalent among the public, and not always re by practitioners of medicine, that the pains co in the muscles and joints of the aged and continuin intervals for years are a long lasting form of the feve swelling and pains in the joints which occurs in attacl few weeks' or days' duration in the young. The anatomy of these two groups of cases is sufficie demonstrate their absolute difference. In what is chronic rheumatism well-marked arthritic changes are such as bony induration, ankylosis, degenerati destruction of cartilage, while permanent morbid c in joints form no part of the post-mortem appearan acute rheumatism, as these may be studied in those p whose death has been due to the consequences of v disease in the first half of life. It is clear fro evidence that the several forms of chronic a have no relation to rheumatic fever. Since it is de to avoid the suggestion of any pathological relat chronic rheumatism the term "acute rheumatism" fall out of use and the words "rheumatic fever" be inv employed.

Various forms of septic arthri [illegible] rheumatism is one, are imperfect [illegible] condition on the side of arthritis, [illegible] carditis several conditions due to ascertainable bacilli doubt sometimes placed under the heading of "Rhe Fever." I shall venture to consider some of these con without relation to bacteriology which at present give that precise guidance which it is likely in futur to offer and without the confirmation of which, determinations can only be regarded as approximate.

In the attempt to define clearly rheumatic feve necessary first to consider two diseases which are son confused with it: gonorrhœal rheumatism and prog destructive endocarditis, often called "malignant carditis" or "ulcerative endocarditis."

The close relation in time to scarlet fever which e regards the arthritis and endocarditis which som appear in that disease makes it unnecessary from the point of view to discuss its differentiation from rhe fever. It would promote clear understanding if the a which sometimes follows a proved urethral growth o coccus were included under the general heading of " rhœa," a term sufficiently expressing that infection, the name "gonorrhœal rheumatism" were to be alto disused. Before the modern improvements in s which have made cases of pyæmia very rare possible to see in the post-mortem room the b some patient with a suppurating operation wound, of whose joints and perhaps his pericardium con pus. This condition of pyæmia is the type of what when an arthritis succeeds the onset and accompan progress of a gonorrhœa. The centre of infection in th in such a case is the urethra, and if the heart sho affected, as it occasionally is in the endocardium o cardium or both, the source of the organisms which in is the urethra just as the suppurating wound is the cen infection and the source of the arthritis in pyæmia. observation which in my experience may be made in such case of complicated gonorrhœa, that the arth never cured while any urethritis remains, shows th gonococci in the urethra are the stock whence those joints are derived. The comparative rarity of endoc in such cases shows that the endocardium, like a joint be regarded as a point on the periphery of the in circle, of which the centre is the urethra. This arth gonorrhœa might generally be distinguished from rhe fever, quite apart from discovery of the urethritis, a true nature may safely be conjectured from clinical ob tions, though the patient have no urethral pain and o occasional urethral discharge, or one in which the prese the gonococcus has not been demonstrated. The swellin tenderness are not confined to joints or even to their diate neighbourhood, but are spread in the line of te or over the area of aponeuroses and fascia. The p fascia is very often affected. There is a sense of stiff the affected joints and both this stiffness and the pai longer than in rheumatic fever. Endocarditis is necessary part of the disease and, as a rule, no physical signs indicating it are present. Permanent damage to a joint often seems about to occur and sometimes does occur.

Out of 11 cases under my care at St. Bartholomew's Hospital during the years 1903 to 1907 the plantar fascia was painful in four, and large areas of the calf and forearm in two others, in addition to the arthritis of particular joints. Marked stiffness was present in seven and led to rigidity of the wrist-joint in one. A raised temperature persisted for three weeks or more in five of the cases without signs of any pleurisy or pericarditis. In one case there was on admission disease of the mitral valve causing regurgitation and in this case pleurisy also occurred during the illness. In the other 10 there were no signs of endocarditis throughout the illness. Permanent damage to joints took place in six cases, slight in five, and accompanied by extensive ankylosis in one. The whole aspect of the disease is seen to be entirely different from that of rheumatic fever in the duration and character of the pains as well as to some extent in their locality, and in the absence of infection of the endocardium and the frequency of permanent damage to joints. The temperature chart is not the same as that of rheumatic fever which is under treatment by salicylates. This difference may be stated briefly by saying that the approach to the line of 100° is generally more frequent during the first three weeks and is more often continued into several weeks than in rheumatic fever.

The clinical distinction of ulcerative endocarditis from rheumatic fever is sometimes difficult, and most observers have, I should think, long remained in doubt whether they have before them two distinct diseases or merely varying results of the same infection. The bacteriological evidence does not at present solve the problem. The two diseases, however, may generally be distinguished by clinical observations. In a case of ulcerative endocarditis the patient is often remarkably contented or even cheerful and has not the pained position and expression common in [illegible] This frame [illegible] and who, in spite of high [illegible] s, is invariably placid and [illegible] n most cases of ulcerative [illegible] rom swelling. Out of nine cases under my care no joint pain existed in seven. The temperature chart, however long the disease may last, always shows high temperatures, [illegible] days of each week. I[illegible] reaches 104° F. often; but in others 103° or 102° is the highest point, and in either case this high degree is reached again and again. Sometimes no cardiac murmurs are heard, more often they are plain and vary a little from week to week. Evidence of emboli, such as enlarged spleen, hæmaturia, or hemiplegia, is o[illegible] arteries of a limb are sometimes [illegible] appear on them or on other vessels. The illness may go on for a very long time, but the patient never recovers. Sometimes it is clear that the patient has had rheumatic fever and had a heart damaged by that disease before the ulcerative endocarditis began. Out of the nine patients above mentioned four had had rheumatic fever years before, and one had a heart which had probably been damaged in relation to scarlet fever. These syn[illegible] to distinguish a case of [illegible] rheumatic fever. It may be added that treatment by salicylates is without any effect on the symptoms or temperature chart of ulcerative endocarditis. My conclusion, from a clinical point of view, is that rheumatic fever is a distinguishable disease of different origin from the other morbid conditions which include arthritis amongst their symptoms.

The cardinal features of rheumatic fever are endocarditis and arthritis. Endocarditis is always present. In most cases, but not in all, it produces some permanent alteration in one or more valves. This endocarditis of rheumatic fever is the chief cause of the varieties of valvular disease met with in patients under 30 years of age. If the heart in a slight case is only auscultated at the beginning and end of the disease the sounds may sometimes seem to be unaltered and it may be assumed that they have been normal throughout; but if the heart is examined daily changes in its sounds will, in my experience, always be discovered, which, taken with the evidence of the frequency of definite valvular disease as a result of rheumatic fever and with the frequency of a history of rheumatic fever in cases of valvular disease belonging to the first half of life, justify the belief that these variations in sound may be taken as evidence of the presence of endocarditis, even though no permanent valvular lesion be produced.

Out of one hundred cases of rheumatic fever under my care in St. Bartholomew's Hospital murmurs indicating valvular disease were distinct in all but one. In the solitary exception, that of a man, aged 24 years, who had first had rheumatic fever the year before that in which I saw him, pericarditis was present with a very loud friction sound which may have obscured an endocardial murmur. The friction sound remained after the fever had disappeared and I was never able to hear any murmur. Many of the patients gave a history of previous attacks, some of them certainly were in their first attack. The slight degree of arthritis which is sometimes present in a first attack of rheumatic fever in a child often leads to its non-recognition by a parent and patients who are suffering from the disease later in life and who have suffered from it more than once before—a very common case—are often found to be very inaccurate in fixing the date. When a child with rheumatic fever is said never to have had an attack before, but is said to have had chorea a year before, it will be far more often true that another attack of rheumatic fever preceded the chorea than that the existing attack is the first one. A patient of the age of 28 years may easily remember an illness of childhood in which he was confined to bed with severe pains in the joints, but slighter attacks of pain are easily forgotten. Every man has his own memory by which to test the powers of memory possessed by others. The recollection of physical pain and of slight illness is especially transitory. Few pains are more severe than that of toothache, but who can mention the dates in his life or even the years in which he had toothache? Even when an event is impressed upon the mind by some special act in relation to ourselves its precise date is rarely remembered even by highly trained minds. The Fellows of this College each receive half-a-crown in the College on the Monday after Palm Sunday, but how many of them could write down on what day of the month those Mondays were or who on each particular occasion sat to their right hand and their left in the Comitia? We generally expect too much from the memory of our patients. I have therefore not attempted to say how many of these one hundred patients with rheumatic fever were suffering from their first attack. 63 were males and 37 were females. As regards age they were thus distributed:—

63 Males.

To 5 years	1	To 25 years	5
„ 10 „	14	„ 30 „	4
„ 15 „	20	„ 35 „	3
„ 20 „	13	„ 40 „	3

37 Females.

To 5 years	3	To 25 years	5
„ 10 „	4	„ 30 „	4
„ 15 „	10	„ 35 „	3
„ 20 „	7	„ 40 „	1

In 44 males and 29 females the mitral valve alone was affected; in nine cases, all of males, the aortic valves alone were affected; in eight males and eight females both the mitral and the aortic valves were affected; in one male the pulmonary and aortic valves were affected; and in one case, as already mentioned, a very loud friction sound made it impossible to determine the presence or absence of valvular disease. In seven other cases, in all of which the mitral valve only was affected, pericarditis was present, so that pericarditis occurred in only 8 per cent. of the whole. The question of whether endocarditis or pericarditis was the more common in rheumatic fever was frequently discussed by the generation which flourished between 1830 and 1860, but at the present day the reply must be that while pericarditis is a somewhat rare incident of the disease there is evidence of endocarditis in every case.

Taking the history of 100 cases of valvular disease lately under my care in which the patients were of the age of 30 years or less, 60 gave a distinct history of rheumatic fever, and in 100 cases in which the patients were over 30 years of age, 46 gave a history of rheumatic fever These 200 patients were none of them included in the 100 cases of rheumatic fever mentioned above. The 200 cases show the frequent occurrence of rheumatic fever as a cause of endocarditis. It is probably correct to say that three-fourths of the cases of valvular disease which are seen in patients under 30 began in the endocarditis of rheumatic fever, and that half of the cases of valvular disease in patients over 30 began in the same disease. The 100 cases may be taken as proving that endocarditis is invariably present in rheumatic fever. It must be regarded as the central condition in the disease. If no evidence of endocarditis is to be found throughout an illness of which a symptom is arthritic pain then that illness is not rheumatic fever, and the arthritis has some other cause.

Sir William Selby Church, one of the latest writers on rheumatic fever, does not believe that endocarditis is invariably present. "It is difficult," he says, "perhaps impossible, to determine during an attack when endocarditis begins, for it gives rise to no special symptoms, but in a large majority of cases if no endocardial murmur be present during the first ten days of an attack the endocardium escapes." This is certainly the prevalent view, but my own observations lead me to a different conclusion. I have found that in every case of first attack of rheumatic fever the presence and sometimes onset of endocarditis may be inferred from the alterations in the heart sounds. In later attacks where valvular disease with a loud murmur or murmurs existed before the onset of the arthritis, minute differences of sound are less easily detected, but progressive alterations in the valves as well as, in many cases, diurnal or weekly alterations of sound, with rises of temperature after arthritic changes have ceased, satisfy the observer that endocarditis is present.

The deepest symptoms of rheumatic fever are alterations of the heart sounds and can only be discovered by a trained observer. The most obvious are pains in the joints accompanied by swelling and often by redness of the skin over them. The patient himself is distressed by the pain and anyone at his bedside may see the swellings or the redness. This part of the disease is matter of common knowledge, while detection of the endocarditis belongs to the arcana of medicine, discoverable only by a skilled method of observation and a trained sense of hearing. This prominence of the external over the internal symptoms was still more marked when, owing to the want of any remedial drug, the pains lasted for more days than they do at present, and at the same time the practice of auscultation was less assiduously pursued than it now is. The well-known fact that the size or number of the joints affected has no direct relation to either the severity of the endocarditis or to the seriousness of the consequent valvular disease supports the view that the endocarditis is the primary lesion in rheumatic fever.

The point of entrance of the organism which seems likely to exist, though its presence has not been proved, has sometimes been suggested to be the tonsils. A slight degree of sore-throat and sometimes a severe angina faucium may be present at the beginning of an attack of rheumatic fever, but is not found sufficiently often to justify the belief that swollen tonsils are the first anatomical change of the disease and that it is through them that the organism enters the system.

The common expression that the pain flies from one joint to another—say, from the left ankle to the right knee—is, of course, merely a relic of the Hippocratic doctrine of metastasis. When an empyema[2] succeeded a pneumonia, or an obvious pleurisy was followed by a pneumonia, the Hippocratic school held that one disease had been converted into another, and thus it was easy for them to regard an inflamed ankle on one side as converted into an inflamed knee on the other. This form of words belonging to an obsolete doctrine ought at the present day to be avoided in teaching medicine at the bedside, since expressions, as distinct from mere terms, of archaic pathology easily continue to have influence on the mind of our own day in a way detrimental to a clear understanding and view of disease.

Whatever the point of entrance and line thence of travel, the endocardium is to be regarded as the invariable centre and primary region of growth of the organism of rheumatic fever and the swollen joints as so many colonial settlements proceeding thence.

The affected joints of rheumatic fever always recover completely; not a single case of stiff joint was to be found i the cases of the last six years in my wards. The knee-joir is one which is very often attacked in rheumatic feve perhaps more often than any other. The presence po mortem of a mitral valve showing thickened edge, thickene tendinous cords, or small growths upon its cords or edge ma be taken as indicating that the person in whose body it found has had rheumatic fever. When I have opened th knee-joints in young patients who have died from the resul of disease of the mitral valve I have never found the remair of changes in the structures of the joint, neither thickenir nor degeneration. Some of these cases may have acquire their affection of the mitral valve otherwise than by rhe matic fever, but the percentage of cases in which mitr disease is the product of rheumatic fever is so large that th exceptions as regards other ways of origination of mitr disease do not affect the argument. In old hospital not any accounts of cases of rheumatic fever terminating in sti joints, or of stiff joints attributed to past rheumatic fever, ma be suspected to have been examples of some form of septi arthritis or of progressive or degenerative arthritis and not true rheumatic fever.

After the endocardium and the joints the temperature rheumatic fever next deserves consideration. The wel known papers of Dr. Henry G. Sutton in the Guy's Hospit Reports for 1865 and 1866, entitled "Cases of Rheumat Fever Treated for the Most Part by Mint Water, *Collect* from the Clinical Books of Dr. Gull," unfortunately give evidence as to the temperature attained or continued wh the disease was left to follow an uninterrupted course, for th thermometer had not then come into regular use in th hospitals of London.

In the 100 cases in my own wards which I have alread mentioned the effect of a treatment by salicylate of so must be allowed for. Doses of not less than 10 grains n more than 20 were given during the febrile period of t disease, for one, two, or three days every four hours, th every six hours for a period regulated by any remains of pa or unusual rise of temperature, and succeeded by a long continuance of administration three times a day. This w the general plan of treatment, the patient being kept in b with a few exceptions till the temperature had been norm for three weeks. The commonest temperature chart was o in which the temperature on admission being 100° or high it rose to a less height the next day, and perhaps still less the third day, and then continued normal for some days, aft which it rose to 99° or a little above 99° on some one day or tw days of a fortnight or three weeks and then steadily continue normal or subnormal for three weeks, after which the patie left the hospital. The slight rise on one day, or continue for two or three days, of the week succeeding a pause several days which itself succeeds the first definite fall temperature to the normal point is characteristic. When th chart presents a different aspect circumstances which expla the greater or longer rise can generally be discovered. A fe examples may be given :—

A girl, aged 10 years, was admitted to the hospital for what seeme to be her first attack of rheumatic fever. On admission her temper ture was 101 5° F., on the next day it was 99 8°, and it was then norm till the sixteenth following day, when it rose to 99 2°. It was the normal for two days, then it rose to 99°, then it was normal for fo days, and then it rose to 99°, after which it remained normal.

A girl, aged 16 years, who had had a previous attack, had a temper ture of 99° F. twice in the first week and one of 98 6° in the secon week, and no further rise.

A woman, aged 20 years, who had had three previous attacks, w admitted with a temperature of 99° F. and on the next day h temperature was 99 8°, on the day after it was 98 6°, on the day aft that 98 8°, and then it was normal or subnormal for 13 days It the rose on two successive days to 99 2° and then it became normal for eig days, then it rose to 98 8°, was next normal for five days, and after th continued for some weeks more, with rises of a degree or a few tent of a degree separated by intervals of several days, finally reaching continuous normal temperature.

A woman, aged 19 years, in her first attack had on admission temperature of 102 8° F. On the next three days it was successivel 101·8°, 99 8°, and 99 4°, and was then normal for two days, then reached 99°, and [illegible] then it was once mor 99° and then it c [illegible]

A boy, aged ni [illegible] mperature of 102 4° On the next two days his temperature rose to 99° and then it wa normal for 15 days. After one day at 98·8° it was normal for three day then on one day 98 8°, and then normal for 18 days, after which he le the hospital.

Variations or interruptions of this course of temperatu are generally due to ascertainable causes and in rheumati fever, as in all other diseases, a constant consideration n merely of the daily temperatures but of the whole chart is important. Pericarditis always produces a rise in temperature of some days and may thus be inferred before a friction sound is audible. A boy, aged four and a half years, who had had pain in his knees for three weeks was admitted with a temperature of 100·8° F. and *his temperature approached*, or slightly exceeded, 100° for eight succeeding days. On the second day of his admission a friction sound was heard over his heart and was audible *for two days.* The abnormal rise of temperature was certainly due to pericarditis. Pleurisy in the absence of bacteriological evidence as to its nature must be believed to be an *actual part of the* cycle of rheumatic fever, and, of course, affects the chart. Bronchitis, common in patients with rheumatic fever, whose hearts are embarrassed by valvular disease of long standing, similarly affects the course of the temperature, though it remains uncertain whether it or the pneumonia which sometimes occurs are a true part of the rheumatic fever. Attacks of sore throat and common colds are other influences to be considered in contemplating the *temperature chart.* Whoever studies cases of rheumatic fever will become convinced that slight rises of temperature are never unimportant, and that considerable rises of temperature at exceptional times can generally be explained if sufficient search be made.

---

[2] Cf. ΠΕΡΙ ΠΑΘΩΝ, cap ix.

The grounds for the diagnosis of rheumatic fever are: (1) evidence of the results of endocarditis; (2) a multiple transient arthritis; and (3) a temperature chart showing an *initial rise followed* after a fall by occasional rises with intervals of normal temperature and with evidence of the existence of some disease for a considerable period, seldom less than three weeks. The diagnosis ought not to be made till these three factors are ascertained. If endocarditis be clearly present without arthritis ulcerative endocarditis, and not rheumatic fever is likely to be the true diagnosis. The same is true if there be a temperature chart of high oscillations with uncertain evidence of endocarditis but signs of disturbed heart and no arthritis. If there are no signs of endocarditis and a multiple arthritis at present, then [illegible] fever is the [illegible]h there be sig[illegible] of the affected joints come to show signs of permanent damage. *It should be added that a culture may be the only way of* ascertaining whether the gonococcus or some septic organism is the origin of the condition which after some resemblance in symptoms to rheumatic fever leaves the patient with a stiff joint.

The term "subacute rheumatism" should never be used, for it suggests an absence of importance which attaches to no case, however slight, of rheumatic fever. Just as the prevalence of the idea that *petit mal* in some way means that the patient said to have it is not an epileptic, while in fact his next fit may be a most serious one, does harm, so the term subacute rheumatism, by suggesting that the case is of less importance than one of rheumatic fever, does harm. The pains are very slight in such cases, but the endocardium is none the less affected and they are often merely periods of slight endocarditis leading to or threatening more severe manifestations in the future.

Every case of chorea in which there is a cardiac murmur, accompanied by rise of temperature, must be regarded as connected with an attack of rheumatic fever, perhaps best as the continuation of such an attack. It is probable that some cases of chorea in which a valvular murmur can be heard but in which the temperature, even when taken regularly for weeks, shows no rise, are also actual continuations of rheumatic fever, and there are perhaps some cases in which the endocarditis is so nearly quiescent that there are neither murmurs nor rises of temperature and which yet have grown out of an attack of rheumatic fever and may pass on into another such attack. Spasmodic and incoördinate movements in children may be due to several causes, but it is important to recognise that what is sometimes called rheumatic chorea is a definite species of which a cardiac murmur due to the same endocarditis as that of rheumatic fever and a temperature showing occasional rises, are symptoms. The first question when a case of chorea is before us is to determine whether it belongs to this species, and if it does the patient for purposes of treatment may be assumed to be in the course of an endocarditis less severe than it is in a definite attack of rheumatic fever but capable of aggravating or producing injury to the cardiac valves and especially to the mitral valve.

The administration of sodium salicylate so commonly relieves the pains in the joints as well as reduces the temperature in rheumatic fever that whenever it is found in any case that sodium salicylate has no effect, even in a large dose, the suspicion will arise that ulcerative endocarditis, a *gonococcal infection, or some other condition* and *not true* rheumatic fever is present.

The disease belongs to the first half of life, though, like measles, mumps, and some other morbid conditions of childhood and youth, it may appear for the first time in the second half of life, but here again the difficulty of certainty as to a patient's true history often raises doubt as to whether his earlier life has been free from any attack. In the absence of bacteriological evidence it is impossible to be certain, but as a result of the observation of a few supposed first attacks between the ages of 35 and 45 years I incline to the belief that rheumatic fever does now and then attack a patient at that age. Before the diagnosis is made great care should be taken to ascertain that no septic source, such as a uterine one in women, exists, or has recently existed, in the patient.

The duration of rheumatic fever is indefinite. The exact day of its commencement can rarely be fixed. In many cases the state of the heart proves that the disease has been in progress for some time before the patient is aware that he has a definite illness. The date of its absolute termination is always obscure. The difficulty of determining it is increased by the knowledge that endocarditis may continue to affect the heart—in other words, that the organism which produces it may continue to live within the heart, capable of fresh development, long after the temperature has become normal. What is commonly called an attack of rheumatic fever probably continues not less than three weeks after a normal temperature is reached. Certainly as this period is approached the temperature shows less tendency to those occasional rises which are common in the first month of the illness. The fact that a patient has not yet recovered from an attack may be indicated by slight rises of temperature, fresh pains or swelling of joints, or even by chorea with or without rise of temperature. *Since there is* generally no further opportunity of infection it is probable that the organism remains in the heart capable of reproducing under favourable circumstances the former phenomena. Thus the duration of the disease really depends on the presence of circumstances which are favourable to the development of an organism capable of long existence in the human body. "When a man is infected by bilharzia," said the very learned Professor Looss to me in course of a conversation on parasitology in Cairo this winter, "it may be some comfort to him to reflect that every entozoon dies after a sufficient lapse of time. What we have to do is to ascertain what its lifetime is" To learn its lifetime is equally part of the study of every micro-organism. The bacillus of enteric fever commonly ceases to be maleficent within three months of its introduction into the human body. Sir George Paget related to me the history of a patient of his who developed signs of tuberculosis of the lung at 30 years of age, was never quite free from signs of it, and died from well-marked pulmonary tuberculosis when over 90 years of age. The tubercle bacillus had lived in his body for full 60 years. The duration of life of the organism of rheumatic fever is certainly less than that of the tubercle bacillus Its active presence, as shown by its effects, lasts longer than that of the pneumococcus in lobar pneumonia. I shall venture to offer a hypothesis as to its approximate duration when I come to consider the prognosis.

The conclusion to which I wish to attain in this lecture is that every case of rheumatic fever, whether the pains in the joints are slight or severe, is a case of endocarditis, and that the condition of the endocardium is not to be regarded as a frequent complication but as the essential and invariable feature of the disease. I cannot help wishing that a name absolutely extricating this serious disease from the confusion involved in the term "rheumatism" could be found. Medical terms, inconstant as their meaning is from century to century, are difficult to destroy. It is no less difficult to bring them into use The "dothienenterite" of Bretonneau was appropriate enough but is almost as little used as the "pædosteosplanchnocace" of Daniel Whistler. Dr. Charles Badham's term "bronchitis," issued just a century ago, owes its firm place in the English language as well as in medical practice partly to the circumstance that no patient likes to think that his lungs are affected, since he knows that people often die from lung disease, but is willing to account for his cough by a name which does not convey a definite anatomical idea to his mind. Remembering this unwillingness of men and women to hear that they have diseases associated with the lungs or heart, I feel that "heart fever," which would be an appropriate term for a disease of which the most serious feature is endocarditis, would have little chance of coming into use instead of rheumatic fever. Were it not for this difficulty on the side of public opinion, which is what chiefly regulates the use or neglect of words, the term "heart fever" might with advantage be adopted for that morbid condition in which endocarditis, transient arthritis, and raised temperature are always present.

THE BLOOD IN RICKETS.

By LEONARD FINDLAY, M.D. GLASG.,

ASSISTANT TO THE PROFESSOR OF PRACTICE OF MEDICINE, GLASGOW UNIVERSITY; DISPENSARY PHYSICIAN, WESTERN INFIRMARY, AND ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

(*From the Pathological Laboratory of University and Western Infirmary, Glasgow.*)

EVER since von Jaksch[1] described his well-known cases of "anæmia infantum pseudo-leukæmica" the relationship of that disease to rickets has been much discussed. In nearly all the records of cases some mention is made of its association with rickets, and, in fact, not a few authors write as if "splenic anæmia of infancy" were merely a severe degree of the anæmia usually described as accompanying rickets. To this rule the Italians form striking exceptions, as they almost universally make no mention of rickets in their reports of cases. Von Jaksch taught that splenic anæmia was of the nature of a primary disease, and a quite distinct clinical entity, while Wentworth[2] and Hutchison,[3] on the other hand, think that it is of the nature of a secondary anæmia. The last-named author considers that it and rickets may be the result of a common, but as yet unknown, cause, while the Italians hold that it is consequent on septic infection, and designate it by the name "anæmia splenica infettiva."

Considering the frequency with which rickets occurs, comparatively seldom has the condition of the blood been the subject of study, and much of the diversity of opinion regarding the nature of splenic anæmia and its relationship to rickets is no doubt due to this lack of knowledge of the blood picture in rickets. Many authors have examined one or two cases, but I have only been able to discover two papers on the subject which are based on extensive observations.

Morse[4] in 1897 reported the result of an investigation into the condition of the blood in 20 cases of active and uncomplicated rickets occurring in children between the ages of seven months and two years. He found the percentage of hæmoglobin (as estimated by the apparatus of von Fleischl) to vary between 48 and 77, the red cells to vary between 3,508,000 and 5,528,000 per cubic millimetre, and the leucocytes between 5500 and 18,800 per cubic millimetre. He observed nucleated red blood corpuscles in three of the cases, all of which presented some enlargement of the spleen; and in one of these, in which the spleen was greatly enlarged, nucleated red cells, both megaloblasts and normoblasts, were very numerous. In nearly all mention is made of some variation in the size of the red cells, and occasionally poikilocytosis was observed. Morse concludes from his observations that most cases of rickets present some anæmia which as a rule varies with the severity of the disease, and that there may or may not be a leucocytosis.

Felsenthal (quoted by Morse) investigated 12 cases of rickets, the patients varying in age from nine months to two years. Three of the patients were very markedly rachitic and had large spleens. He got practically the same result in all the 12 cases. The red blood corpuscles were not decreased in number, or only to a very slight extent, but the hæmoglobin was always diminished. Nucleated red cells only occurred in the most severe cases.

Esser,[5] in a recent paper on the Etiology of Rickets, discusses the condition of the blood so far as the number and character of the leucocytes are concerned. He asserts that there is almost invariably, at least in the early stages, a marked leucocytosis, amounting in some instances to 30,000 per cubic millimetre, and that the nuclei of the polymorphonuclear leucocytes are more lobulated than normal. He does not, however, give any table of his results, nor does he make any mention of the percentage of hæmoglobin or number of red blood corpuscles.

Holt,[6] Cheadle,[7] and Ashby,[8] in their writings on rickets, speak of there always being a more or less severe anæmia, but not one makes any mention of a specific example. Text-books on hæmatology repeat this opinion. Ewing[9] and Cabot[10] both assert that in rickets there is a variable degree of anæmia, proportionate to the severity of the rachitic manifestations. Cabot says that anæmia is always present, and that examples of polychromatophilia, normoblasts and myelocytes, are not infrequently observed. Hutchison,[11] on the other hand, states that severe rickets is often accompanied by no appreciable degree of anæmia, and Pfaundler and Schlossmann[12] say that in rickets there is nothing characteristic in the blood.

Throughout the literature of splenic anæmia are records of isolated or perhaps two examples of rickets examined by one author, but in the majority of instances mention is made of some degree of splenic enlargement, and in not a few of these cases the blood picture was found similar to that met with in splenic anæmia. It should be remembered, however, that in splenic anæmia the size of the spleen bears no definite relationship to the severity of the anæmia, and also that it is very doubtful, in view of recent observations, if uncomplicated rickets is accompanied by any degree of splenic enlargement, and, as Starck[13] has shown, that splenic enlargement is as common in non-rachitic as in rachitic children.

It was to elucidate this question, the condition of the blood in active and uncomplicated rickets, that the present work was undertaken, and the subject was studied both from the experimental and clinical aspects. The experimental findings will be published later, and in the present paper I intend to confine myself chiefly to the discussion of the results as found in the cases of spontaneous rickets in children.

Spontaneous rickets.—I investigated the blood picture in 30 cases of active and uncomplicated rickets in children varying between the ages of 12 and 42 months, and to control these results blood examinations were carried out in 12 healthy children of corresponding ages and belonging to the same class of society. Some were absolutely healthy and others were the subjects of such conditions as hernia, cleft palate, and hypospadias, conditions which, it will be admitted, do not affect the blood picture. The rachitic cases for the most part were collected from patients attending the outdoor department of the Glasgow Hospital for Sick Children during the spring of 1907 and the spring of 1908. All the observations were made at the same time of the day—between 11 A.M. and 1 P.M. I contented myself with single observations, and, as some might raise objections to the reliability of such examinations, it may be stated that the present work was commenced after I had obtained several years of almost daily practice in this kind of work. When one has obtained a certain amount of experience in such work the personal error becomes reduced to a minimum, and the reliability of isolated examinations undoubted. Moreover, is it not as a rule on the result of a single observation that a diagnosis often rests?

At each examination the hæmoglobin was estimated by Gowers's hæmoglobinometer, and the red and white cells were enumerated with the Thoma-Leitz hæmocytometer, using dilutions of 1 in 100 and 1 in 10 respectively. Films were also made and stained with both Jenner's and Ehrlich's triacid fluids, and a differential count was made; the number of leucocytes counted varied between 400 and 800. Every case was examined *after treatment with Jenner's fluid* and many after the use of Ehrlich's triacid stain, especially when there was any dubiety as to the presence or absence of granules in the cells.

[13] Quoted by Wentworth, Boston Medical and Surgical Journal, vol. cxlv., p. 491.

It may be advisable in this connexion to indicate the exact significance which I have attached to the terms by which the different types of leucocytes are designated. 1. In the classification of neutrophile, eosinophile, and basophile polymorphonuclear leucocytes and myelocytes I have used as criteria those laid down by Ehrlich and about which all authors will agree. 2. As hyaline cells I have named all

large mononuclears with an oval or slightly indented nucleus and a relatively large amount of clear and faintly staining protoplasm, entirely devoid of granulations. 3. As transitional cells I have classified all those with a markedly bilobed nucleus and clear protoplasm devoid of granulations. The protoplasm of some of these cells did contain an occasional metachromatic granulation as stained with Jenner's fluid, but after staining with Ehrlich's triacid stain no granulation was detected. 4. Under the heading of "Lymphocytes" I have included all cells, irrespective of their size, which have a relatively large and centrally or slightly eccentrically placed nucleus, surrounded by a smaller amount of markedly basophile protoplasm often showing at the margins a certain degree of fraying. These cells varied much in size—from less than to twice that of a red blood corpuscle. The nucleus often showed several slight indentations, and in not a few one or two nucleoli were observed. These cells contained no granules. 5. I have classified apart under the term "Mononuclears with metachromatic granulations" a cell which it was often difficult to say was hyaline, lymphocytic, or myelocytic in nature. It was of very variable size, and it possessed a circular or slightly oval nucleus frequently showing several small indentations. The nucleus was relatively large, and it stained more deeply with basic dyes than did that of the typical lymphocyte. The protoplasm varied much in amount and density, and contained a variable but usually small amount of faintly staining metachromatic granulations. Sometimes at one part of its circumference the protoplasm was markedly basophile like a lymphocyte, and at another part quite hyaline in character. In films stained with Ehrlich's triacid fluid no trace of granulation could be detected. All gradations between this cell, the lymphocyte, and the hyaline were observed. This type of cell has been described by Naegeli, who considers it lymphocytic in nature. My reasons for classifying this cell apart were (1) the difficulty of deciding as to its exact nature and (2) that in rickets it was decidedly more numerous than in the case of normal children.

I have considered it advisable in the consideration of the cases of spontaneous rickets to tabulate the results in groups according to the age of the patient. The 30 cases have been divided into five groups, each of which comprises an age-period of six months. Under each group will be found a table giving detailed accounts of each of the rachitic and normal cases of corresponding ages, and a secondary table comparing the averages of the rachitic and of the normal cases with the reputed average (of authors) for that particular period of life.

Group A, Table A (comprising cases between the ages of 12 and 18 months).—In this series of cases it will be observed that in all except No. 5 the rachitic condition was marked. Not one of the children was walking, and in none was there any enlargement of the spleen noted. With the exception of cases Nos. 2 and 4 there was absolutely no evidence of anæmia. In case No. 2 the hæmoglobin was diminished only 5 per cent. and in case No. 4 the red blood corpuscles were some 500,000 per cubic millimetre below the normal average. In no case was a nucleated red blood corpuscle observed. In one case (No. 3) there was a leucopenia, while in the other four the number of leucocytes was slightly above the average, but there was nothing which could be called characteristic excepting the large numbers of the mononuclear cell with metachromatic granulations.

In one of the controls, No. II., a perfectly healthy and lively child, the hæmoglobin only amounted to 64 per cent. and the leucocytes numbered more than in any one of the rachitic children. The most striking features in the above table are the relatively higher blood counts and less variation in number of leucocytes than in the normal cases. These points will be better appreciated by comparing the average of the results in the rachitic cases with the average of the controls and also with the accepted average blood estimations as quoted by Hutchison and Carstanjen.[11]

—	Hb.	Red cells.	Leucocytes.	Absolute number per c.mm. of—		
				Neutrophil polymorphs.	Lymphocytes.	Mono nuclears with metachromatic granules
Rachitic cases.	83	5,558,000	13,720	4122	5185	3218
Controls ..	74	5,175,000	16,800	6049	9164	827
Reputed average.	70	5,000,000	12,500	5250	5375	—

Group B, Table B (comprising cases between the ages of 18 and 24 months).—In all of these cases the rachitic manifestations were marked, and with one exception they had not as yet learned to walk. The spleen in two of the cases was palpable, but in one only on deep inspiration, so that there was in all probability no marked enlargement of the organ. The hæmoglobin in all the cases was above normal, and with the exception of Case No. 6, in which the red cells were 800,000 per cubic millimetre below the normal average, there was no oligocythæmia. In one case (No. 11) one nucleated red cell was observed while counting 400 leucocytes, and in this case there was also a distinct degree of leucocytosis, but this child had been suffering from diarrhœa for some days prior to the examination. The other cases presented a varying degree of leucopenia. Here again the mononuclears with metachromatic granules were fairly abundant. The absence of anæmia, on the contrary the richness of the blood, will be better exemplified by comparing the averages as before:—

—	Hb.	Red cells	Leucocytes.	Absolute number per c.mm. of—		
				Neutrophil polymorphs.	Lymphocytes.	Mononuclears with metachromatic granules.
Rachitic cases.	86·6	5,383,333	10,533	4832	3470	1456
Controls .	79 5	6,160,000	11,500	3478	7450	363
Reputed average.	70	5,000,000	11,000	4950	4950	—

Group C, Table C (comprising cases between the ages of 24 and 30 months).—In four of these cases the rachitic manifestations were marked and in one very marked. Not one of the children was walking, though two had walked at an earlier period of life, only, however, to go off their feet later. In one case the spleen was palpable on deep inspiration. Two of the cases presented a reduction of the hæmoglobin to the extent of 4 per cent. and 15 per cent., and in two the red cells were diminished to the extent of 250,000 and 760,000 per cubic millimetre below the normal. In one case two nucleated red blood corpuscles, both of normoblastic type, were observed while counting 400 leucocytes. Four of the cases presented a certain degree of leucocytosis due both to a polymorphonuclear and lymphocytic excess. Here, again, comparison of the averages shows that though the blood count of the rachitic cases is inferior to that of the controls it is decidedly above the accepted average. There is, however, a slight leucocytosis and the cell with metachromatic granulations is still unduly abundant.

—	Hb.	Red cells.	Leucocytes	Absolute number per c.mm of—		
				Neutrophil polymorphs	Lymphocytes	Mononuclears with metachromatic granules.
Rachitic cases.	87	5,166,000	15,440	6789	6562	797
Controls...	94	5,606,000	11,966	5559	5283	523
Reputed average.	80	5,000,000	10,500	5040	4414	—

Group D, Table D (comprising cases between the ages of 30 and 36 months).—In two of the cases the rachitic condition was slight; in two it was marked, and in one it was very marked, and with the exception of one of the n some brown discharge was found in the vagina. was normal, but the body of the uterus was found nctly enlarged, and the sound passed $3\frac{3}{8}$ inches. I r to have the cervix dilated, so that the endo- might be explored; this was accordingly done terwards in a nursing home. For the dilatation, e inserted, and the dilatation was completed under ia next day with Hegar's dilators. On passing the to the uterine cavity a polypus of the size of a large was found. It was of firm consistence, and its nent to the uterine wall was quite definite and circum- . I removed the polypus in the usual way and sent a n of it for examination to the Laboratories of Public n. The report on it was as follows: "This tissue has ructure of a very adenomatous polypus. Some of the s are cystic, the stroma is infiltrated with inflammatory acts, but the tissue is benign." The fact that the pus was non-malignant was the more important as the ent had a feeble, dilated heart, and Dr. F. W. Hewitt, who e the anæsthetic, considered she would not have stood a jor operation such as abdominal hysterectomy.

---

[11] Goulstonian Lectures, Lecture I., THE LANCET, May 7th, 1904, p. 1253.

ASE 2.—This patient was a woman, aged 70 years, who d been married 45 years, and had had three children, the st 35 years previously, and four miscarriages all before the rst child. The menopause occurred at the age of 50 years. he came to see me in December, 1908, and said she had een losing blood almost constantly, but not in large amount, for at least 18 months. When she was not bleeding there was a "sticky" vaginal discharge. She had had some backache, but no severe pain. On examination the os uteri was a little patulous, but the cervix was otherwise normal. The uterus was not well felt bimanually, as the patient was exceedingly stout. The sound, however, passed $2\frac{3}{4}$ inches, causing slight bleeding. This patient was admitted shortly afterwards into the London Hospital under my care. The cervix was dilated in the same way as in the preceding case, and a polypus almost exactly similar in size and in microscopic structure was found and removed.

I may add that in July, 1907, I showed a specimen at the Obstetrical Society of a fibroid polypus removed from a patient, 72 years of age. In this case the polypus projected into the vagina through the dilated os uteri. It was the occurrence of bleeding which led to an examination and the discovery of the polypus. Microscopical examination showed that the polypus was not malignant. These three cases are, I think, instructive in showing that even at such advanced ages as 70, 72, and 73, the tissues of the uterus may in very rare instances depart from the state of quiescence which then so generally characterises them, and take on an activity leading to the production of benign tumours similar to those so frequently found in adult life before the occurrence of the menopause. Such cases are, however, in my experience very rare; and it should be remembered that, as bleeding after the menopause is so very generally due to the presence of a malignant growth, the benign character of any growth which may be removed in such circumstances should only be accepted as proved after careful microscopical examination.

Another cause of bleeding after the menopause, not due to malignant disease, of some interest is the growth of an ovarian tumour. It is only, however, in rare cases that metrorrhagia is found associated with the growth of an ovarian tumour after the menopause while on the other hand ovarian tumours are common in elderly women. It is not clear why in the majority of such cases there is no metrorrhagia if a causal relation exists between the two conditions. In a certain number, however, it appears that such a relation does exist, since after the removal of the ovarian tumour the metrorrhagia ceases, and does not recur. I recorded some cases of this kind in THE LANCET of Jan 2nd, 1897, p. 23, and also in THE LANCET of June 16th, 1906, p. 1674.

Upper Brook-street, W.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The spring meeting of the South-Eastern division of the Medico-Psychological Association will be held by the courtesy of Dr. E S Pasmore at the Croydon Mental Hospital, Upper Warlingham, on Tuesday, April 27th. Dr. Pasmore kindly invites the members to luncheon to 1 30 P.M. Dr. Thomas Claye Shaw will read a paper upon the Clinical Value of nsness in Insanity.

AN ENORMOUS FÆCAL TUMOUR IN A GIRL WITH CONGENITAL ABNORMALITIES OF HER PELVIC VISCERA.

BY H. B. BUTLER, F.R.C.S. EDIN.,
ASSISTANT MEDICAL OFFICER TO THE ROYAL SURREY COUNTY HOSPITAL, GUILDFORD;
ARTHUR F. HERTZ, M.A., M.D. OXON., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL;
AND
W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL.

A GIRL, now aged 16 years, was in St. Thomas's Hospital as an infant because of a congenital abnormality of her rectum. Nothing was done at the time, but her mother was advised to bring her to the hospital when she was a few years old for operative treatment. As the child's general health remained very good this was not done. Her first stool was passed three days after birth, and she became gradually more and more constipated, until, at the age of eight, a month or six weeks frequently elapsed before she opened her bowels. Sometimes after an unusually long period of constipation, fluid fæces would run away from her constantly for about a week. She had also occasional attacks of pain, but her appetite was always good, her tongue clean, and her colour good. She was well developed and was accustomed to take plenty of exercise in the open air. Medical advice was never sought for her until Dec. 15th, 1907, when she was admitted into the Royal Surrey County Hospital, Guildford, under the care of Mr. H. B. Butler. Her temperature was 102° F. and her pulse was 120. Her tongue was furred and she looked ill. She complained of severe abdominal pain. The abdomen moved well on respiration, but it was very tender, especially over the right side. A hard, non-fluctuating tumour, dull on percussion, was found coming up from the pelvis; it resembled in size and position a uterus at the sixth month of pregnancy. On examination under an anæsthetic it was discovered that the patient had no anal canal, her rectum and vagina ending in a common cloaca. The rectum was found to be full of fæces and it appeared probable that the whole tumour was fæcal. A quantity sufficient to fill three large kidney dishes was removed by a blunt spoon; the fæces contained several plum-stones. The tumour did not completely disappear, so aperients and enemata were given during the next three days, with the result that considerable quantities of fæces were evacuated. The temperature steadily fell and was norma on Dec. 18th. The tenderness had completely disappeare but a tumour of the size of a cricket-ball was still present the right iliac fossa. The temperature rose on the eveni of the 18th and fluctuated between 99° and 101° until 26th, when the patient was again anæsthetised and incision was made over the mass. Coils of intestine found adherent to each other and to the parietal periton A second more lateral incision was made, but the pat condition did not warrant the long dissection which have been necessary to penetrate between the inte loops in order to reach the tumour, so the first incisi closed and the second was packed with gauze. The and pain now disappeared, and on Feb. 2nd the pati the hospital apparently well, the wounds having hea the tumour having disappeared.

On May 16th Mr. Butler was again called to patient, whose temperature was 102°. A painful was found in the right iliac fossa. She was readm the Royal Surrey County Hospital and an incision over the mass, which was found to be an intra abscess. This was evacuated and the wound soon the temperature fell to normal. On August 8th the tumour had reappeared, the bowels not having b since May 16th. She was sent to Guy's Hospital was admitted under the care of Dr. A. F. Hertz the picture of health, was well nourished, with a healthy skin, moist clean tongue, and good appetite was excellent. The lower part of the completely filled with a very hard tumour, well- and laterally, rising out of the pelvis to a dist

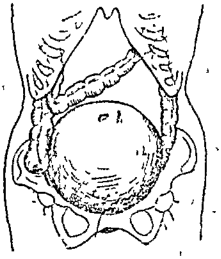
inches above the pubes, its transverse diameter being eight inches. It was not fixed to the abdominal wall and could be displaced by manipulation as much as the crowded condition of the pelvis allowed. It was dull on percussion and could be pitted by prolonged pressure with the finger, the depression remaining for, some time. The urine contained no albumin, pus or casts, and the circulatory, respiratory and nervous systems were quite normal. By means of a bismuth meal it was found that the cæcum, ascending colon, transverse colon and descending colon were normal in size and position, except that the transverse colon was pushed upwards by the tumour. The rate with which the bismuth traversed the colon was also normal. The shadow ended about one and a half inches below the left iliac crest, where the iliac colon apparently joined the enormously distended pelvic colon and rectum, which together formed the sac filled with fæces. The accompanying illustration shows somewhat diagrammatically the relation of the sac containing the fæces with the rest of the colon, as ascertained by the skiagraphic examination



On August 12th the patient was anæsthetised and placed in the lithotomy position. By means of two fingers inserted into the rectum and pressure exerted from outside on the tumour the fæcal mass was slowly dug away; subsequently a tube was introduced into the rectum and the irrigation, combined with the use of the finger, enabled the whole accumulation to be removed. The colon was then irrigated until, two hours after the manipulations had begun, the water came away perfectly clear. By weighing the patient before and after the operation it was found that five pounds of fæces had been removed. The fæcal tumour having now been removed, it was possible to investigate more accurately the nature of the congenital abnormality. There was no trace of an anus, anal canal, or sphincter, the rectum opening into the posterior part of a cloaca. The opening had at first admitted one finger only, but it had been stretched until two fingers could be introduced into the rectum. The latter was separated by a transverse fibrous septum from two vaginæ, which were separated from each other by a median septum, which joined the transverse septum posteriorly. A cervix was found in both vaginæ, but only one uterus could be felt; the greater part of the latter was on the right of the middle line. Probably the septum between the vaginæ was continued into the uterus, the condition being that of "uterus bilocularis." The patient was ordered abdominal massage and faradism and was put on a full diet and allowed to get up. She was given strychnine and cascara sagrada. Whenever her bowels were not opened for 48 hours she was given an enema of cold water. The patient unfortunately insisted on leaving the hospital within a week of the removal of the fæcal accumulation, so that there was no time to ascertain whether the treatment would be effective. Although her mother was instructed to give her enemata regularly she failed to do so. It was, therefore, not surprising that the fæces began to re-accumulate in the rectal sac. When seen on Oct. 24th a large fæcal tumour was again present in the abdomen, somewhat smaller than on the last occasion, and situated more in the left than in the right half of the lower part of the abdomen. In spite of the retention of fæces the patient looked and felt exceedingly well, and was able to walk 12 miles without fatigue. She was, however, much troubled by the continuous escape of small quantities of fluid fæces, apart from which she was unable to produce any evacuation.

The patient was readmitted into Guy's Hospital under the care of Mr. Arbuthnot Lane on Oct. 30th. On Nov. 2nd the fæcal accumulation was again removed under an anæsthetic by the finger with the aid of continuous irrigation, the process lasting two hours. The next day Mr. Lane operated by an incision through the left rectus. The largely dilated and hypertrophied gut was exposed and divided about four inches from its lower extremity, the distal portion being closed and dropped into the pelvis. The proximal portion was pulled out of the wound till the residual bowel was taut. It was then sewn in position, means being taken to constrict the orifice sufficiently. At the operation the lower end of the large intestine was found to have contracted to a considerable extent. It was completely free from all adhesions and the mucous membrane of the excised portion was subsequently found to be quite normal. Adhesions were seen in the right iliac fossa; it appears probable that the abscess previously opened in this situation was appendicular in origin and quite independent of the fæcal tumour. The abdominal examination showed that only a single, apparently normal, uterus was present. The patient made an uninterrupted recovery and was discharged on Nov. 27th. At the end of March, 1909, she was perfectly well and very pleased with the result of the operation.

Apart from the remarkable size of the fæcal tumour and the interesting developmental abnormalities, the case is noteworthy as showing how in some cases prolonged retention of large quantities of fæces may occur without producing any anatomical or functional changes. Thus there were no adhesions round the distended intestine; the musculature had not suffered greatly in spite of the long period during which it had been greatly stretched, as the gut was found at the operation to be contracted down almost to the normal size; and the mucous membrane was found to be perfectly healthy on both naked-eye and microscopical examination. Lastly, the patient at no period showed the smallest signs of autointoxication, her complexion being excellent, her nutrition good, and her mental and bodily activity quite normal.

DELAYED DELIVERY IN A CASE OF CENTRAL PLACENTA PRÆVIA,

WITH REMARKS ON THE TREATMENT OF THE LATTER.

BY N. I. SPRIGGS, M.D., B.S. LOND., F.R.C.S. ENG.,
LATE HOUSE SURGEON AND OBSTETRIC RESIDENT, GUY'S HOSPITAL.

ON April 17th, 1907, I was called to a woman who was in labour and had been flooding freely. She was a multipara, aged 40 years, and had had 13 full-time confinements and one abortion at three months. In her first labour instruments were used and the perineum was badly ruptured. She said she had "carried all her children high" and the labours were "long and dry." When seen the patient had evidently bled very freely, though the exact quantity of blood lost could not be ascertained. She was blanched and the radial pulse could only just be distinguished. She considered that she was eight months pregnant. On examination the placenta was felt presenting through an os about the size of a five-shilling piece. It could not be determined in which direction the nearest edge of the placenta lay. There were no pains. A saline rectal injection was given, the patient directed to drink freely, and one drachm of liquid extract of ergot administered, as there seemed to be no possibility of any obstruction, and the labour was rather premature. A few hours later the pulse was considerably better, in spite of the fact that the patient had been vomiting. The whole hand was then inserted into the vagina (which was more easily performed than usual on account of the old rupture of the perineum) and the full length of two fingers inserted through the os, but still, on sweeping round the entire circumference of the latter, no indication of the edge of the placenta could be found.

Three courses were now open: (1) to put the whole hand through the os uteri, and so reach the edge of the placenta for the purpose of turning; (2) to try to deliver the placenta first (after Sir James Simpson); this would also need a hand through the os uteri; and (3) to perforate the placenta. The latter procedure was adopted as being the most suitable, as the patient was not under an anæsthetic, neither was she in a very good condition to take one; also the os was not as yet fully dilated. A hole was scratched through the placenta with the finger and the head found presenting. The bleeding was very slight. Bimanual version was then performed. This was very difficult and took some time, as the hole in the placenta was only made big enough to admit two fingers, and the fœtal parts could only be distinguished with great difficulty by the extreme tips of these fingers. As soon as a foot could be felt an attempt was made to rupture the membranes on the fœtal aspect of the placenta, but without success, as they were very tough. The rupture was accomplished, however, with the help of a pair of rather sharp-pointed uterine forceps. The hole in the membranes and placenta was stretched bigger by opening the blades of these forceps. This allowed some liquor to escape and the leg was then brought down. After placing a tape round the foot the patient was left, as there were still no signs of any pains. Eight hours later it was found that the leg had only very slightly advanced. A few slight pains had been present, but had passed off again. The patient's pulse was 120 and very weak and she had been continually losing a little blood. An examination showed that the hole made in the placenta, which was bounded by what felt like moderate-sized vessels or strands of placental tissue, was too small to let the half-breech freely descend, as the latter was tightly embraced all round. The hole was accordingly freely torn larger with the fingers and gentle traction applied to the leg. The child was then delivered in about 15 minutes and was found to be dead. After waiting half an hour the placenta did not come away, though one edge could be felt in the vagina. The uterus was then explored and found to be irregularly contracted, retaining one portion of the placenta which was also slightly adherent. After the placenta had been completely removed and a uterine douche given the womb contracted well.

On examination of the placenta after delivery it was found to be situated approximately in a central position, as the presenting part nearly corresponded to the place of insertion of the cord, which was in the middle of its fœtal surface. The rent made through the placenta had, however, extended to the edge during the process of delivery. The placenta was not observed to be exceptionally large in extent, though this would be expected from the fact that one edge was found to be adherent to the uterine wall near the fundus, whilst the opposite edge was free in the vagina. This point should have been more exactly observed, and I can only plead in extenuation that early morning hours in a comfortless and none too clean tenement are not conducive to exact pathological observation.

The after-history of the case was as follows. There was slight pyrexia for two days, which then subsided. Later the patient had some thrombosis in the right femoral vein which delayed complete recovery. At the time of writing (three months after delivery) she is getting about and doing her work as usual.

The chief points of interest in this case may be briefly summarised as follows:—

1. *The very central position of the placenta.*—I have not come across any records of series of cases indicating the rarity of this central position, with the exception of a small series of 34 cases of placenta prævia recorded by Sinnetamby,[1] and of these only one was central. If one may judge by the scanty attention given by most text-books to the subject of the treatment of placenta prævia when thus centrally situated, this position is of considerable rarity.

2. *The delay in delivery*, apparently due chiefly to the fact that the hole in the placenta and membranes was not, in the first instance, made sufficiently large to allow the half-breech to descend freely. This is a cause of delay to which attention has not yet been called, as far as I am aware. The half-breech generally forms an admirable dilator and stimulator of the cervix, but in this case it was held up by the placenta, so that only the thinner part of the thigh was through the os, and this part was not of sufficient girth to stretch and stimulate it. The placenta was of normal thickness and therefore was not easily torn or moulded round the half-breech as a thinner one might have been by such very feeble pains as the patient was having.

3. *The inertia of the uterus.*—This is common in such cases and is due to the weak and anæmic state of the patient, the want of the normal stimulation of the cervix, and possibly to some disturbance of the uterine "polarity" due to the abnormal placental implantation and to the frequent prematurity of the labour.

4. *The retention of the placenta.*—This may very easily be explained in this case by the irregular and feeble contraction of the uterus. This retention is more common in cases of placenta prævia than in normal labours, as is emphasised by De Lee.[2] In two cases of central placenta prævia recorded by Peters[3] the placenta had to be removed manually in both. In the present case a dose of ergot was given when the patient was first seen, and it is doubtful whether the irregular or hour-glass contraction observed 12 hours later was *post hoc* or *propter hoc*. It may have been due to the disturbed polarity alluded to above.

5. *The value of saline injections* was well illustrated in this case. This is also emphasised by Sinnetamby[4] in the paper to which reference has already been made; at the same time he advocates very slow delivery in cases of placenta prævia.

6. *The very slight amount of hæmorrhage* which accompanied perforation of the placenta in this case.

7. Lastly, *the treatment adopted*—viz., perforation of the placenta as far as the membranes, bipolar version, perforation of the membranes, and slow breech delivery.

On referring to the text-book instructions, Galabin[5] says: "In the case of a very central placental insertion it may be necessary before performing the actual version to rupture the membranes along the edge of the placenta, to draw that edge downwards towards the centre of the os, and then to proceed with the version as rapidly as possible"—i.e., Galabin apparently considers that perforation is never necessary. Jellett, in his excellent "Manual of Midwifery," does not mention the fact that the presence of the placenta causes any difficulty in performing bimanual version. Braun von Fernwald,[6] in a paper on the Treatment of Placenta Prævia, advises separation of the placenta from the lower uterine segment till the membranes are reached—practically the same as Galabin. He also mentions the slight risk of air embolism attending this procedure. Palmer[7] mentions two cases of central placenta prævia in which forceps were used, but in the majority of such cases the presence of the placenta would interfere very much with their application, and it is extremely unlikely in such cases for serious hæmorrhage to be delayed till the os uteri is enough dilated for forceps.

Sir James Simpson recommended complete separation of the placenta and its delivery before the fœtus in certain cases, and it would seem that centrally situated placentæ are the most suitable for this form of treatment, as they have to be so very largely detached before the fœtus can be delivered. Also it appears that spontaneous delivery of the placenta first, which sometimes occurs, and which gave rise to this form of treatment, occurs more often when the placental site is very low, and this is only to be expected when one considers that the tendency would then be for the presenting part to push the placenta before it. R. Barnes[8] recommended digital separation of the placenta around the whole circumference of the os uteri, and in the case of a centrally situated placenta this treatment approaches to that of Sir James Simpson alluded to above. It must be noted, however, in these cases that the placenta is often very large in extent, and so reaches a good way from the os uteri in all directions, so that it is unlikely that complete separation could be accomplished with the fingers only through the os. Peters, in the record of his two cases of central placenta prævia, mentions that perforation often causes serious hæmorrhage. R. Barnes[9] says on this subject "we can imagine a case in which perforation might be *excused*." Finally, we may gather from the above views that the general opinion is that perforation of the placenta is rarely, if ever, needed. In spite of this, it is difficult to see what better could have been done, in the exigencies of general practice, for a case such as that upon which these remarks are based.

ON THE TERMINATION OF THE THORACIC DUCT.

BY F. G. PARSONS, F.R.C.S. ENG.,
LECTURER ON ANATOMY, ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, ETC.;
AND
PERCY W. G. SARGENT, M.B., B.C. CAMB., F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND SURGEON TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE, ETC.

(From the Anatomical Department of St. Thomas's Hospital.)

THE wounding of the thoracic duct during operations at the root of the neck is an accident which, until quite recent years, was regarded as a very grave injury, usually followed by death. In the 1895 edition of Erichsen's "Surgery" it is stated that "the injury has been almost universally fatal." That this is not necessarily so has since been abundantly proved by the published cases, of which W. J. Stuart[1] has collected and tabulated 40. Of this series only five died, and even some of these five deaths appear to have been in no way due to the wounding of the thoracic duct. Stuart estimates the true mortality as probably not greater than 8 per cent., and it is interesting to note that amongst the cases in which the accident was recognised at the time of operation and the duct ligatured there was not a single fatality. In Keen's "Surgery" (1908) E. W. Andrews remarks that "if ligated, distension and rupture will follow unless collateral branches divert the flow;" and again, "ligation involves some theoretical risk, since with a single duct the patient must die unless it can discharge."

Such considerations led us to seek in the anatomy of the terminal portion of the duct some explanation as to why the older surgeons regarded a wound of the duct as such a serious accident, and why the ligation of the duct should appear to be in reality so free from danger. On referring to the literature we find that Poirier and Cunéo[2] state that the termination of the duct by two distinct branches is fairly frequent. Watson[3] says that sometimes the terminal part of the bend of the duct bifurcates and opens by two separate trunks into the subclavian vein. We have only been able to find two definite series of observations, one by Verneuil[4] and the other by Wendel.[5] The former found that out of 24 cases the duct was single in 18, double in 3, triple in 2, and six-fold in 1. The latter found that out of 17 cases, it was single in 9, double in 3, three-fold in 1, and multiple in 4.

We now submit a further series of anatomical observations, based upon 40 records, 36 of which are from subjects within 24 hours of death, 1 from a living case in which the termination of the duct was exposed but not cut in the course of an operation, and 3 from careful dissections of formalin-hardened specimens. Our plan was to isolate the duct in the posterior mediastinum and inject it with coloured gelatin, after which it was followed up to its termination. We found that in 18 out of the 40 cases the duct divided and that this division usually occurred while it was lying behind the left common carotid artery about 5 centimetres from its opening. In one case, however, the division only took place 8 millimetres from the termination, while in another the duct was double for 2 centimetres.

As a rule the duct divided into two branches of about equal size, though when they were unequal the upper—i.e., the one most liable to injury—was usually the larger. This we noticed six times and we met with no cases in which the lower branch was markedly larger than the upper. In three out of the 18 cases of bifurcating ducts one of the two branches divided again and the three ducts thus formed communicated with one another by anastomosing channels, so that a wide-meshed plexiform arrangement was present. In two others the division was still more free and there were four openings into the great veins.

It does not follow that because the duct divides before its termination it necessarily has more than one opening into the veins. In only nine of the 18 double or multiple ducts was this the case; in the other nine the branches united, sometimes in the wall of the vein, but more often before reaching it, and so only one aperture was present. When there was only one opening, whether the duct had been single or double before (we opened the veins in an extra specimen to make up for the one seen during life which, of course, could not be opened), that opening was usually into the lower part of the internal jugular vein below and often under cover of the left flap of the valve which is there. This was the case in 26 of the 40 specimens, and the material at our disposal leaves us little room to doubt that it is normal. In three cases the opening was anywhere between the point of junction of the two veins and one centimetre above, but in addition to these 26 there were two other specimens in which the openings were respectively 19 millimetres and 25 millimetres above the junction.

Only three times were we able to satisfy ourselves that the opening was really into the junction of the internal jugular and subclavian vein. Of the nine cases in which the duct had two or more openings four had two openings close together and one had four openings close together in the normal place—i.e., into the lower part of the internal jugular within one centimetre of its junction with the subclavian. One had one opening in the normal place and another higher up in the internal jugular above the valve. Two had one opening in the normal place and another into the subclavian. One had one opening in the normal place and three others close together in the subclavian.

It is interesting to notice that in only three out of our 40 cases did the duct open partly into the internal jugular and partly into the subclavian, because Lower[6] regarded this mode of termination as the normal. It is also worth while drawing attention to the fact that in only two of the 40 cases were more than two openings present, so that the case which Verneuil records in which there were six openings is probably a very rare one.

For convenience of reference we may tabulate the different methods of opening in the following way:—

A.	Single ducts opening into the lower centimetre of the internal jugular vein	19
B.	Single ducts opening into the junction of the internal jugular and subclavian veins	3
C.	Double ducts joining and opening into the lower centimetre of the internal jugular	7
D.	Double ducts joining and opening more than one centimetre above the junction of the internal jugular and subclavian	2
E.	Double ducts with two openings into the lower centimetre of the internal jugular vein.	4
F.	Double ducts with two openings, one into the lower centimetre of the internal jugular, the other into the same vein higher up	1
G.	Double ducts with two openings, one into the lower centimetre of the internal jugular, the other into the subclavian vein	2
H.	Multiple ducts with four openings all into the lower centimetre of the internal jugular vein	1
J.	Multiple ducts with four openings, one into the lower centimetre of the internal jugular, the other three into the subclavian	1
	Total	40

By adding together cases A, C, E, F, G, H, and J, it will be seen that in 35 cases out of the 40 cases the duct opened wholly or partly into the lower centimetre of the internal jugular. From the foregoing it will be noted that in nearly half our cases (18 out of 40) the duct was double and that if a surgeon accidentally divided one of these in the root of the neck it is unlikely that, provided the wound was occluded by ligature, any inconvenience would result. It is, of course, unwise to found a definite percentage on 40 cases, but our experience with statistics of other parts of the body makes us believe that the range of error is not likely to be very great, while the difficulties and tediousness of procuring suitable material, injecting and dissecting the specimens must serve as our apology for not presenting a larger series.

It does not follow that even if the duct does not divide in the neck its section must necessarily give rise to serious symptoms because it has been pointed out that occasionally there is a communication in the thorax between the thoracic duct and the right lymphatic duct, and if this were present the chyle might be diverted to the veins of the right side. We did not find this communication injected in any of our specimens, but our dissection seldom went lower than the fifth thoracic vertebra. Moreover, the main duct has sometimes been found to open into one of the azygos veins.[7] No doubt the division of the thoracic duct in the neck is a remnant of its plexiform character in lower mammals. In the ox, for example, a plexiform termination is normal, according to Chauveau, while in the horse, pig, dog, and cat a division and reunion so as to form a ring is very common. The union between the thoracic and right lymphatic ducts is a repetition of the avian arrangement where the duct opens into the precaval veins of both sides.

[6] Quoted by Poirier and Cunéo, loc. cit.

In four out of our 18 cases of double ducts we noticed that the vertebral vein passed between them, which is not surprising when it is remembered that the duct sometimes passes in front of, and sometimes behind, the root of this vein. In one case the branches passed one in front of and one behind the first part of the subclavian artery; this was a specially plexiform termination and had four openings into the veins. As a rule, however, nothing passed between the two or more terminal branches when they were present.

The subclavian, jugular, and broncho-mediastinal ducts were seen on several occasions, though the injection never passed into them. The subclavian duct was most often seen and was always remarkable for being closely connected with a lymphatic gland of moderate size (from 1 to 2 centimetres) which lay near the outer border of the scalenus anticus. Out of 12 cases in which it was dissected out, this duct joined the thoracic duct in ten, while in the other two it opened separately just below the opening of that duct. The left jugular duct was seen ten times and in nine of these it opened into the thoracic duct. This observation is of little value, because in those other cases where the duct was not seen it probably opened somewhere else. In one of these cases there were two jugular ducts, one joining the thoracic duct and the other opening into the internal jugular vein a few millimetres higher up. The usual place for the jugular duct to join the thoracic duct was 1 to 2 centimetres from the termination of the latter. The broncho-mediastinal duct was only seen four times, and probably often opens separately into the great veins. In all these four cases it opened into the thoracic duct some distance from its termination.

During our investigations of the termination of the duct into the great veins it was necessary to open the latter, and in doing so we gained some definite knowledge of the jugular vein. In 32 out of the 40 cases the valve consisted of two pocket-shaped semilunar flaps which were almost always right and left, though the right one often had a tendency to be somewhat anterior and the left posterior. As a rule these two flaps were not set on quite horizontally, but their anterior ends were higher than their posterior. In most cases the valve was about one centimetre above the termination of the internal jugular, though in a few cases it was a good deal higher. Of the eight exceptional cases one showed complete absence of the valve and in another it was very rudimentary. In three specimens only one cusp was present, but that was in every case the left. In three specimens there were three cusps, and in all of these the extra cusp was very small and was situated on the posterior surface of the vein between the hinder attachments of the other two.

The actual opening of the thoracic duct was almost always obliquely through the wall of the vein and having a direction downward, forward, and to the right. Usually there was a dilatation in the venous wall forming a pouch resembling the ampulla of Vater in the duodenum, and the mouth of this, when the duct was empty, played the part of a valve or pair of valves. In a few cases the orifice was guarded by a permanent fold of endothelium, but more often the valves disappeared on stretching the wall of the vein and, though physiologically functional, could not be described as definite morphological structures. In three of the 40 cases the vertebral vein opened into the above-mentioned pouch, but in most of them it opened a little lower down into the back of the junction of the internal jugular with the subclavian vein. More rarely the opening was distinctly into the innominate vein, though seldom more than a few millimetres to the right of a line continuing down the inner margin of the internal jugular vein.

The point of opening of the left superior intercostal vein was seen in almost every case and was always into the innominate below and to the right of the orifice of the vertebral. Its exact point of opening, however, varied greatly.

Summing up the contents of this communication, we noticed: 1. That the thoracic duct divided in the root of the neck in 18 out of 40 cases (nearly 50 per cent.) 2. In 9 of these it joined again, in 7 it opened by two orifices, and in 2 by four orifices. 3. In 35 of the 40 cases (87·5 per cent.) the duct opened wholly or partly into the lower centimetre of the internal jugular vein. 4. That it usually opened into a pouch and that the opening of this acted as a valve, though a definite morphological valve was only occasionally seen. 5. That the duct passed sometimes in front, sometimes behind, and sometimes on both sides of the vertebral vein. 6. That the internal jugular valve was a very constant bicuspid structure rarely absent, but occasionally tricuspid or unicuspid. Comparing our results with those of the two smaller series referred to, we find that our proportion of multiple ducts is much greater than that of Verneuil, ours being 18 out of 40 and his being only 6 out of 24; whilst our figures agree closely with those of Wendel, 8 multiple out of 17, who also used injected ducts for his dissections.

We conclude that, as there appear to be multiple ducts in nearly half of all cases, some at least of the reported cases of injury must have involved damage to a division and not to the whole duct, the ligature of which would cause no serious hindrance to the chylous flow into the veins. In the few cases which have recovered spontaneously after chylorrhœa of many days, or even weeks, it is probable that a second channel already existed, either of the common kind which we have described or of some rarer sort, such as a large communication with an azygos or some other vein.

EPSOM SALTS AS A POISON:

WITH A RECORD OF A CASE OF UNUSUAL SYMPTOMS D TO THIS DRUG.

BY CHARLES FRASER, M.A., M.D. EDIN., D.P.H. CAM

As a therapeutic agent Epsom salts are *commonly* co sidered to be particularly free from danger. There are, ho ever, records of six cases in which the administration *of th* drug was followed by untoward symptoms of a very grav character, five of these rapidly terminating fatally. Ther appears to be considerable room for debate as to the mann in which the salt exerts its morbid effects. In registerin another case of "poisoning" by this drug I have for purpos of comparison and contrast appended summarised reports o these six cases, and at the same time I have ventured to offe suggestions as to the probable modes of action of the drug.

At 2.30 P.M. on August 19th, 1908, I was summoned t see a boy, aged three and a half years. The patient's mothe stated that 25 hours previously, during her temporary absenc from the room, the patient had taken a heaped-up tea-spoonful of Epsom salts from a packet which he had found lyin on the table, imagining it to be sugar. Finding his mistake but wishing to remove traces of his guilt, the little fellow washed the salts down with a mouthful of milk. On returning to the room a few minutes later she found him retching and apparently suffering considerable pain in the stomach Nausea and retching continued throughout the day. About 7 P.M. the abdominal pain, which was of a griping, spasmodic character, was very severe, and actual vomiting became a prominent symptom. Thirst was also very distressing. There had been no action of the bowels. At this stage a pharmaceutical chemist was consulted who prescribed castor oil; this was at once rejected. Throughout the night the patient continued to suffer severe pain and vomited at frequent intervals. No further assistance or advice was sought until 2.30 P.M., although in the meantime the child had rapidly become worse.

The boy was now obviously critically ill. He lay in bed on his back, his face pinched, eyes sunken, and skin pale. His mind was perfectly clear. About every two minutes he had colicky attacks which made him draw up his legs. The temperature was 100·5° F.; pulse 160 and small; tongue was very dry, the papillæ standing out prominently. Thirst was intense; the bowels had not acted. About half an ounce of urine had been passed during the 24 hours. The abdomen was very distended and rigid; the skin was markedly hyperæsthetic, so much so that palpation was performed with difficulty. This hyperæsthesia was least over the epigastric region, where the percussion note was tympanitic; in both iliac regions and in the hypogastrium it was dull. A catheter was passed and about half an ounce of dark muddy urine was drawn off which contained no albumin and was very acid. At 9.30 P.M. the patient seemed weaker; he was still very sick, vomiting every few minutes small quantities of greenish-yellow stuff which had no characteristic odour. The bowels had not acted; temperature was still 100·5° and the pulse 160. The distension was more pronounced; the percussion note was more generally tympanitic, the dulness being limited to the left iliac region. At 2.30 A.M. on the next day vomiting was as incessant as before; neither bowels nor kidneys had acted; the pulse was uncountable and the temperature 100·5°. There seemed, however, to be rather less tenderness on palpating the abdomen and the dulness was still limited to the left iliac region; the liver dulness seemed normal. The symptoms and appearances being suggestive of acute peritonitis, laparotomy was deemed advisable and the patient was at once removed to the Sussex County Hospital.

---

[7] Wendel, loc. cit.

For the following notes I am indebted to the kindness of Mr. A. H. Buck, under whose care the patient was admitted.

"On admission the child was collapsed; temperature sub-normal; pupils dilated; pulse 160; abdomen rigid and retracted with very slight movement. Laparotomy performed about 3 30 A.M. Central incision made; on opening abdomen intestines floated up into the epigastrium; about two pints of blood-stained serum let out; no lymph; no smell. (This blood-stained serum was submitted to the pathologist, who reported that it was sterile.) Large intestine drawn out and lumps of fæces and gas present; appendix healthy; through small intestine green matter seen as in vomit; bladder was felt to contain about half an ounce of urine. No cause for obstruction found. Drained with rubber tube and gauze plug.

First 24 hours.—Temperature rose to 100·6°; pulse about 170; child very ill and restless; vomited frequently, bright-green stuff at first and later yellow; no fæces or flatus passed in spite of enemata; constantly cried for something to drink; quantities of blood-stained serum continued to drain away; dressing changed four-hourly; child moribund; fed on albumin water and brandy, and rectal saline not retained.

Second 24 hours.—Child still moribund; pulse practically [illegible] every hour; temperature 101·5°. In the afternoon flatus and fæces passed and again after enema; catheter passed at 9 P.M. and one ounce urine drawn off.

Third day.—Bowels opened frequently; urine passed naturally; temperature falls to normal; child much better; wound healing; no discharge from wound.

The child now made an uninterrupted and complete recovery."

Remarks.—That the illness was directly due to the salts will at once be conceded. The child had been in perfect health up to the moment of taking the dose. He then became acutely ill. Now a medium-sized teaspoonful of Epsom salts is found to weigh about half an ounce—a very large dose for a child of this age. The earliest symptoms, as one would expect, were those of gastric irritation, undoubtedly produced by the action of the undissolved salt. The condition of shock which developed later might conceivably have been due to the same cause, the violent stimulation of the sensory nerve endings in the stomach-wall leading to vaso-motor paralysis, splanchnic engorgement, and depletion of the rest of the body. The nervous system being also in a state of tension owing to the fear of punishment would possibly tend to make the liability to shock greater. Having no corrosive properties Epsom salts could not give rise to perforation of the stomach wall. The appearance, therefore, of symptoms of acute peritonitis was probably due to some mischief further along the alimentary tract. The fact that on opening the abdominal cavity no peritonitis was found did not simplify matters, and the presence of blood-stained serum in the absence of any likely cause for intestinal obstruction made diagnosis still more difficult. The suggestion has been offered that as a result of taking the salts there may have been a volvulus or intussusception causing the effusion of serum. This volvulus or intussusception, it has been urged, could very easily be reduced during the operation (or as the result of the anæsthetic before the abdomen was opened) without being recognised and without necessarily leaving any evidence of its having been there.

Against intussusception is the fact that there were no purging and no tenesmus. The bowels had, in fact, not acted at all. The occurrence of volvulus, on the other hand, is compatible with the violent retching and vomiting. The diagnosis of the condition is notoriously difficult at all times. Whilst this theory, however, accounts for most of the symptoms and appearances prior to the operation it is less easy to reconcile it with the condition of things during the first 24 hours after operation. The persistence of the constipation, the result of paralysis of the bowel, might have been a feature of that state of depression of all the vital functions which is incidental to the condition of shock. The vomiting, however, is not so readily explained. But in the absence of any other explanation of the presence of blood-stained fluid in the abdominal cavity one feels disposed to accept this view.

The extreme rarity with which cases of poisoning by Epsom salts occur is illustrated by the fact that the following six records embrace a period extending from 1841 to 1896. After a pretty thorough perusal of likely sources of information I have failed to trace any other case. This is all the more surprising when one considers the extreme frequency with which the drug is administered and the heroic manner in which it is often dispensed.

CASE 1 (*Taylor's case*).—An old man whose bibulous habits were well known to his neighbours became the victim of a practical joke at the hands of two of his associates. These men, it appeared, added very large quantities of Epsom salts to his beer. On drinking several pints of this medicated stuff he was suddenly seized with violent purging and died in 48 hours. The mucous membrane of the alimentary canal was found to be inflamed and Taylor adds "there was no doubt that death was due to the irritant effect."[1]

The fatal issue here appears to have been due to the purgative action of the irritant. By causing very rapid loss of fluid from the body it gave rise to the condition of collapse, and the fatal result was doubtless accelerated by the degenerated condition of aged and alcohol-poisoned tissues. This case is the least interesting of the group. The action described is not peculiar to this salt but is common to all cathartics when administered in very large doses. The case, however, is referred to in the older books on toxicology as a classical instance of poisoning by Epsom salts.

CASE 2 (*Christison's case*).—A boy, aged 10 years, was given two ounces of salts, partly dissolved and partly mixed in a cupful of water, by his father, who thought that he was suffering from worms. Immediately on swallowing it he was noticed to stagger and fall. When seen by his medical attendant half an hour later the breathing was slow and difficult, the pulse was imperceptible, and the whole frame seemed to be in a condition of great debility. He died in 40 minutes. There had been no vomiting or purging and there were no morbid appearances after death. "This case shows," says Christison, "that in certain circumstances the laxative neutral salts may be irritating enough to cause death."[2]

One may reasonably infer from this history that death was due to syncope. The large dose—the morbid action of which was, no doubt, intensified by the fact that part of it was undissolved—on coming into contact with the stomach wall of a very youthful subject initiated powerful afferent impulses which reflexly brought about that cardiac exhaustion which is a prominent feature of the case.

CASE 3 (*Neale's case*).—A boy, aged 15 years, took one ounce of salts in solution on an empty stomach 24 hours before he came under the physician's observation. There had been three very small motions. A few hours after he had taken the dose he felt sick and this symptom continued throughout the night. The following day he tried to work but had to give up the attempt. Vomiting continued at frequent intervals. When first seen he was lying in an

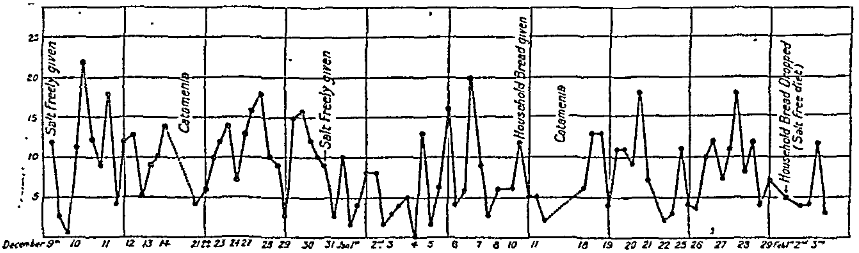
[2] Christison: On Poisons, p. 574.

this tumour there was œdema of the leg, while above it the thigh was normal. Whilst resting no œdema of the left leg was present, but it developed after she had been walking about several hours and always rapidly disappeared. No local cause was discovered, neither was there anything in her past history to suggest thrombosis. In general appearance she was a healthy, well-developed woman; anæmia was not present and she was not cachectic. She had no cardio-vascular changes. The heart's apex beat was in the fifth space and was not dislocated outwards, while on auscultation the pulmonary second sound was louder than the aortic second sound. Ophthalmoscopic examination revealed no changes in the discs, and the average blood pressure was between 120–130 mm. of Hg. For the *first two days of* her stay in hospital no albumin was found in the urine; on the third day it was present in large quantities. Microscopic examination revealed the presence of hyaline and granular casts; while the proteids were found to be albumin and globulin; no albumoses were present. On two other occasions, on Nov. 19th and Jan. 4th, the urine had been free from albumin. Between Nov. 12th and Dec. 9th one specimen of urine was tested daily for albumin by being boiled and acidified with acetic acid. The amount of albumin present was found to vary within very wide limits. On some days the urine boiled solid, on others only a faint cloud would be present, so that from Dec. 9th until her discharge, whenever practicable, the percentages of albumin were tested by Esbach's method. Three specimens daily were usually examined and the fluctuation in the amount of albumin present was noted. (See Chart.) The average quantity of urine voided daily was between 25 and 26 ounces; the maximum quantity observed during her residence in hospital was 40 ounces. With rest in bed the œdema of the right leg and the œdematous mass in the popliteal space [illegible] was allowed to [illegible] its original pr[illegible] placed on a rigidly salt-free diet and it was then found that the œdema rapidly subsided, though she was allowed to take exercise as before. Since then to the date of her discharge on Feb. 4th she has been confined to food containing no salt or to a diet containing household bread instead of salt-free bread, and no return of the œdema was observed, though, as *would be expected, the amount of albumin present in the* urine varied widely as before.

Several interesting features were presented by this case. The most prominent was the localisation of the œdema, the main position of which was in the right popliteal space, and the fact that for six years it was unilateral. In addition the entire absence of cardio-vascular changes secondary to the lesion in the kidneys is noteworthy, together with the fact that on four separate occasions albumin was completely absent from the urine. In spite of the large amount of albumin lost daily her general health was very good and she exhibited none of the anæmia and cachexia so frequently present in patients suffering from chronic Bright's disease.

In conclusion, I have to thank Dr. J. Rose Bradford for his courtesy in permitting me to publish in more detail the features of this case, a short account of which has appeared in the Proceedings of the Royal Society of Medicine.



The figures on the vertical column indicate the number of grammes of albumin excreted per litre of urine.

THE TREATMENT OF BRONCHIECTASIS BY THE CONTINUOUS INHALATION OF OXYGEN (STOKER'S METHOD).

BY W. P. HERRINGHAM, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON FORENSIC MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

A YOUTH, aged 20 years, was admitted into St. Bartholomew's Hospital, under my care, on Oct. 20th, 1908. He was a small, ill-developed, thin fellow. He had had no illness until 18 months ago, when, while ship's cook on board a trawler, he had been seized with an illness the leading symptoms of which were cough and pain in the side. He had never been well since, and had for a long time been spitting a copious and offensive discharge. The left side of the chest was shrunken and the heart was drawn outwards. The lower part of it was very dull, and resonance in the upper part was impaired. There were signs of a cavity near the apex and râles all over the rest of the lung. The temperature was normal; the sputum was repeatedly examined for tubercle bacilli without result, and tuberculin injections of 1-400th and of 1-200th cubic centimetre (O.T.) produced no rise of temperature. An injection of 1-80, which was given three days later, was followed by a fever lasting three days, the temperature reaching 104° F., which I believed to be due to some other infection. Calmette's reaction was negative. The sputum was full of staphylococci and streptococci, and at first amounted to from 8 to 12 ounces a day. It was extremely offensive. On Nov. 9th he began to inhale oxygen in a small stream continuously for six hours a day out of one of the bags invented by Dr. George Stoker for the purpose, which I borrowed to make trial of the method. He continued to do so until Dec. 2nd, when I stopped this treatment, and for purposes of comparison began the inhalation of creosote vapour in the chamber which we have built for the purpose at the hospital. On the 16th I began the oxygen again and continued it until Feb. 2nd, when he was discharged.

The points to which I wish to draw attention are: (1) the amount; (2) the odour of the sputum; and (3) the general feeling of the patient under the treatment. From Oct. 20th to Nov. 8th the sputum was from 8 to 12 ounces in amount and extremely fœtid. The oxygen was begun on Nov. 9th. The following are my notes: "Nov. 13th. Sputum for the last three days has averaged only 4 ounces. It is much less fœtid. Cough is less and he has much better nights. 17th. Sputum averages 3 ounces. 24th. Sputum now 2½ ounces. *Dec. 1st. Sputum averages 2 ounces,* has only a mawkish smell, no fœtor. Oxygen discontinued. 2nd. Creosote inhalations begun. 8th. Sputum averages 4 ounces. 15th. Sputum averages 5 ounces; is more offensive than when he was taking oxygen. Coughs more. 16th. Oxygen begun again. 21st. Sputum averages 1½ ounces, less offensive. 28th. Sputum averages 1 ounce, hardly smells at all," and so it remained. There was no question about his own opinion or that of the sister of the ward. He liked the oxygen far better than the creosote; he felt better, and ate better while under its influence. I may add that in my opinion he undoubtedly did better and looked better.

I do not think there is any more troublesome complaint to treat than this of offensive sputum with bronchiectasis. It appeared to me to be just the sort of case in which oxygen inhalations should be tried. They are much less unpleasant than creosote, and they appear to me to have been in this case much more effective. I should strongly recommend it for similar cases. I will add that as this man was a mouth-breather I stuck a small vulcanite tube, like the mouthpiece of a pipe, into the end of the tube leading from the bag of oxygen, and put it in his mouth. It was no trouble to him.

Wimpole-street, W.

A NOTE ON A CASE OF CYSTIC OVARY.

By Grenville P. Jones, M.R.C.S. Eng., L.R.C.P. Lond.

On March 13th, 1908, I was called to see an unmarried woman, aged 23 years, who for the last three years had been complaining of a persistent dull aching pain in the left iliac region. Though better at times she was never quite free from the pain. During the past 12 months she had been practically confined to the house, spending most of the time in bed. Catamenia were very irregular and painful, and she often went three or four months without a period. She had been treated medically for some time and her symptoms were looked upon as neurotic.

On examination of the abdomen it was found to be much distended with flatus, but nothing else abnormal could be made out. She was ordered a mixture containing small doses of magnesium sulphate for two weeks, which relieved the distension, but the pain remained as bad as ever. I then asked my partner, Dr. G. M. Sharpe, to administer an anæsthetic so that a complete investigation into the symptoms could be made. I found, on a bimanual examination, some thickening in the left ovarian region but no more definite condition. As, however, she had been complaining for such a long time and was now unable to leave the house through the pain, I decided to open the abdomen. This was done through the sheath of the left rectus muscle, when we found the left ovary to be entirely cystic. In size it was only slightly larger than the opposite ovary. The left Fallopian tube was congested and unhealthy-looking, and there were several old adhesions between it and the intestines. I removed both the tube and ovary and closed the wound in the ordinary way. The patient made an uneventful recovery and is now walking about, not having had any return of the pain since the operation.

This case shows how essential it is to examine these patients, with apparently neurotic symptoms, under an anæsthetic.

ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Experiments and Experiences—P[illegible] Clinical—with Heart Tonics.—Action [illegible] upon Each Other.

A meeting of this section was held on April 6th, Dr. T. E. Burton Brown, the President, being in the chair.

Dr. J. Gordon Sharp read a paper entitled "Experiments and [illegible] and Clinical—with Heart Ton[illegible] p said he had examined many specimens of tincture purchased in the open market, and of these several had been found to be inert, having no action on the frog's heart. With the aid of a pharmacist he had endeavoured to find out some of the causes which led to inert preparations being sold: (1) leaves other than those of digitalis might be collected, and unless the batches were examined by someone knowing the characteristics of the leaf error might occur; and (2) a more important cause was improper drying, because if the leaves were allowed to steam the ferment contained in the plant would break up the glucosides. The action on the frog's heart when the tincture was injected into the dorsal lymph sac was next discussed, and Dr. Sharp said that digitalis differed in its action from squill and strophanthus. It did not so certainly stop the heart as strophanthus, but when it did so the ventricle might be found still while the venous sinus and auricles were beating. He emphasised the importance of having preparations of digitalis, squill, and strophanthus pharmacologically standardised. In discussing the action of the drug in man Dr. Sharp said almost the only way of judging of the effects of digitalis or other heart tonic was an indirect one—namely, whether the drug under consideration would remove a cardiac dropsy after rest in bed had failed. To credit any substance as a heart tonic because it appeared to tone up the pulse, lessen the area of heart dulness, or relieve palpitation was evidence of an uncertain character, because there was room for so much divergence of opinion on these points. Dr. Sharp said digitalis acted much more quickly than was generally supposed. He considered the tincture as the handiest preparation; when it was rejected the drug could be given in pill form. It acted most quickly when it was given in doses as large as could be tolerated. Digitalis was the only real heart tonic. 2. Squill preparations were not so often found to be inert as digitalis or strophanthus. They acted energetically on the frog's heart and in poisonous doses appeared to wear out the heart by its energetic action. However, in actual practice these acted up to a certain point and then failed entirely. Their chief use was as an adjunct to digitalis. 3. Strophanthus preparations were often found to be inert in the past, but within the last three years so much attention had been directed to the importance of having standardised preparations that this difficulty would disappear. The drug acted with certainty in the frog's heart and in poisonous doses appeared to stop it in all its anatomical parts simultaneously. In man its diuretic action seemed to be direct—namely, on the secretory tubules of the kidney—as opposed to the indirect diuretic action of digitalis (and in part so in squill) through the circulation. Although it did not act in cardiac dropsy like digitalis, it might by its stimulant action on the kidneys produce a certain amount of diuresis. Given in 20 to 30-minim doses of the tincture it had in many cases of cardiac dropsy a general analgesic action without any real effect on the dropsy. It gave comfort to the patient.

Dr. William Bain read a paper on the Action of Digestive Ferments upon Each Other. He referred to numerous experiments which he had made and described some of these in detail, pointing out the practical application of those results in treatment.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.—Henoch's Purpura.

A meeting of this section was held on March 26th, Dr. E. Cautley being in the chair.

Mr. P. Macleod Yearsley showed a case of a Peculiar Form of Word-deafness successfully treated by the Oral Method. The child could not appreciate heard speech, which she merely repeated aloud, but when she was able to see the speaker such seen speech (lip reading) was immediately answered rationally. The word-deafness apparently prevented the higher centre being effective, but she had now learnt to understand by lip reading. After practice with great effort heard phrases were now understood and answered without the motor response of repeating the question. Mr. Yearsley thought that it was difficult to explain the case on any hypothesis other than that of weakness of the auditory centres.

Dr. H. C. C. Mann exhibited a specimen of a Tumour of the Left Suprarenal obtained from the body of a child aged two years. The growth was 7 inches long by 4½ inches broad. The kidney lay at its lower pole. The growth extended through the diaphragm, invading the pericardium and left lung. The left pleural cavity contained nearly a pint of blood-stained fluid and showed small secondary growths. The cervical glands were sarcomatous. Secondary deposits were also found in the orbital plates, in the right parietal bone, and in the sternum. The child came to hospital with a history of six weeks' weakness and anæmia. A leucocyte count showed 15,000 white cells; hæmoglobin and red cells, 60 per cent. The tumour, which was apparently splenic during life, enlarged rapidly under observation. It moved well with respiration. Death occurred two months later. The tumour was a round-cell sarcoma.

Dr. Cautley showed: 1. The brain from a case of Cerebral Diplegic Spasticity, which had been shown to the section on Feb. 20th, 1909. The whole of the frontal and parietal regions was converted into a bilateral cystic form, bounded mesially by a wall containing a moderate amount of brain substance. According to the history, the child had been healthy till the age of seven weeks and then had an illness which could be accounted for as encephalitis or meningitis. The post-mortem appearance made it more probable that the condition was congenital, dependent on developmental error in the prosencephalon. 2. A specimen of Congenital Heart Disease, showing transposition of the *aorta and pulmonary artery. The right ventricle was the* larger and gave off a normal aorta, from which the great vessels arose by a common origin. The left ventricle gave off the pulmonary artery which was stenosed on account of two of its valves being adherent. There was a small opening in the interventricular septum and the foramen ovale was patent. The ductus arteriosus was normal. The child lived till 11 months, showing moderate cyanosis and clubbing. The heart was enlarged to the right of the sternum. There was a systolic pulmonary murmur and a systolic murmur heard at the apex and behind.—Dr. F. S. Langmead said that there was a specimen in the Museum of Great Ormond-street Hospital which closely resembled Dr. Cautley's first case. It showed some narrowing of the small cerebral vessels.—Dr. G. Carpenter said he had neither seen nor read of a case like Dr. Cautley's, but had seen a locular cystic condition which Dr. A. Ernest Jones reported was, in his opinion, syphilitic. *During life the child had been spastic, with head retraction,* and showed atrophic patches in its choroid.

Dr. A. J. Jex-Blake showed a female child, aged seven years, with Congenital Heart Disease. She had a good colour and weighed 28 pounds. Over the pulmonary area a continuous murmur could be heard, loudest during systole. It could also be heard over the whole chest back and front.—Dr. T. R. C. Whipham thought there were one or two small glands to be felt in the neck. If the *murmur was not due to glands he would agree that it was* caused by a patent ductus arteriosus.—Dr. G. de B. Turtle asked whether the murmur varied in intensity from time to time. That was so when it was due to enlarged glands.—Dr. Cautley thought that it was a purely systolic murmur and was inclined to ascribe it to some pulmonary stenosis and patency of the interventricular septum than to any other defect, because there was so much hypertrophy. The child had not grown well, which he thought meant a bad prognosis.—Dr. Jex-Blake replied that the murmur had not been noticed to grow louder or softer at different times.

Dr. Carpenter showed a case of Congenital Malformation of the Heart, showing a patent ductus arteriosus with bicuspid aortic valves. The child died at the age of three months. During life there was a systolic murmur, best heard over the third left space, just inside the nipple line, conducted towards the left clavicle. The left side of the heart was the larger. *The right ventricle was dwarfed.* The foramen ovale was closed.

Dr. Whipham gave a pathological report upon the specimen of Congenital Cystic Disease of the Kidneys showed at the section on Jan. 22nd, 1909. The sections showed small cysts with a great increase of connective tissue. The tubules were mostly dilated but many were contracted. The glomeruli were somewhat contracted but Bowman's capsules were dilated. The arteries were thickened. The pancreas showed some *fibrosis and thickening* of its vessels. The bile-ducts of the liver were dilated and convoluted. T[illegible] ctive tissue.—Dr. F. Pa[illegible] es in the portal fissures [illegible] bile vessels. In that [illegible] cystic liver.

Dr. [illegible] and photographs of a case [illegible] petigo in a boy, aged four [illegible] of hæmophilia or of syphilis in the patient or his family. The fluid from the bullæ contained degenerated blood corpuscles, but no growth of organisms could be obtained by cultivation. From the impetigo lesions a mixed growth of staphylococcus albus, citreus and streptococcus was obtained. The patient was given boric baths, and the bullæ either were punctured or burst spontaneously, leaving deep sloughing ulcers. Under treatment with hydrogen peroxide, chinosol baths, and balsam of Peru dressings the ulcers cleaned and the condition was now cured.—Dr. G. Pernet referred to a paper he had read on Bullous Impetigo Contagiosa in Children who had Pediculosis. The purpuric condition was more unusual. He thought, in the present case, that the purpura was of streptococcal origin.

Dr. Whipham showed a case of Transposition of the Viscera in a girl, aged eight years. There was a mitral systolic murmur at the heart's apex. The child had had chorea twice.—Dr. Cautley thought that such cases were not so uncommon as one was led to believe in books. He believed that prognosis of life was just as good as if the heart were not transposed.—Dr. F. J. Poynton and Dr. F. Langmead *thought that if the heart was on the right* side of the body there was greater liability to endocarditis.—Dr. Parkes Weber asked whether proposers for life assurance should be rated up if the viscera were transposed?—Dr. Whipham thought not.

Mr. C. L. Addison showed (1) a case of Ankylosis of both Hip Joints ascribed to Scarlet Fever, and (2) a Case of Syphilitic Osteoperiostitis.—Dr. Cautley asked what treatment had been adopted in the second case, and Dr. E. I. Spriggs asked whether *the tissues or fluids had been* examined for the spirochæta.—Mr. Addison replied that after operation the general conditions had improved under mercury and iodide. There was still a sinus over the tibia. Spirochætæ had not been looked for.

Dr. Poynton showed a case of Congenital Symmetrical Swellings on both Heels in a girl. His view was that they were lipomata.—Dr. Pernet agreed.

Dr. Carpenter showed a microscopical specimen of the liver from a case of Icterus Neonatorum in a child, aged 19 days. She became jaundiced on the second day. The navel was healthy. The stools were green. There was a systolic murmur over the left pulmonary area and in the left axilla. Post mortem, the liver was not enlarged, but its section was a deep mahogany colour with large visible veins. As far as the bile ducts could be traced they were empty and not obstructed. Microscopically, the liver cells were crammed *with bile granules of an olive-grey colour. The fine bile* capillaries were filled with inspissated bile in irregularly shaped masses, and showed a moniliform outline.—Dr. Spriggs said that it was not necessary for there to be gross blockage for the production of obstructive jaundice, not only in the condition of toluylenediamine poisoning, but in acute yellow atrophy and phosphorus poisoning. It was probable that the jaundice occurred because of the catarrh of the small bile-ducts. That might also account for liver cells containing particles of pigment.—Dr. Poynton referred to tw[illegible] in [illegible] pr[illegible] He did not think that such cases were common.—Dr. Parkes Weber referred to cases in which several children of the same parents had had jaundice, some of them having died.

Dr. J. Porter Parkinson read a paper upon three cases of Henoch's Purpura. Case 1 was a boy, aged eight years, who suffered from pain in the legs and abdomen and a purpuric rash over most of the body and limbs. The spleen could be felt. The urine contained albumin and occasionally a trace of blood and casts. The abdomen was tender in the epigastric and right iliac regions, and there was occasional vomiting. The child was treated with two injections of horse serum without any improvement, but recovered and was discharged with the urine still albuminous. Case 2 was a *boy, aged six years, suffering from abdominal pain and* vomiting. There were purpuric spots all over the extensor aspects of the limbs. The abdomen was not tender. The urine contained albumin and occasionally blood. In hospital he was suddenly attacked with abdominal pain and the abdomen became tender in the left lumbar region. The pain continued on and off for nearly two months, occurring in crises every two days. Blood was found in the stools during most of this time. Later the face became puffy, especially *the lips and eyelids, but the child began slowly to improve.* The treatment was at first calcium chloride and later three injections of horse serum. Two fresh groups of purpuric spots appeared while the child was taking calcium. The third case, under the care of Dr. Charles Bolton, was a boy, aged six years, who came into hospital with severe pain and passing blood in the stools with a measly non-purpuric rash and coryza. On the next day he vomited and passed blood and mucus by the rectum. The abdomen becoming distended, it was thought that intussusception might be present and the abdomen was opened but none found. There were flecks of lymph in the peritoneum with some appearances of general peritonitis. The boy died on the following day. At the necropsy there was general peritonitis and on the small intestine were 13 hæmorrhagic extravasations of about the size of peas and projecting on both outer and inner surfaces of the intestine. About a foot from the iliac valve there was a collection of much larger hæmorrhages. The small intestine was distended with gas, and the large intestine as far as the splenic fissure, where for about six inches it was quite dark from diffuse hæmorrhage, thickened, and looked almost gangrenous. The diagnosis lay between measles and Henoch's purpura, the suspicion of intussusception not being verified. Dr. Parkinson thought that it was a case of purpura, but the absence of blood and albumin in the urine was unusual. The case supported a suggestion of Mr. Hugh Lett made in the Reports of the Society for the Study of Disease in Children that it is advisable not to operate for intussusception in a case of Henoch's purpura unless an abdominal tumour can be felt.—Mr. HUGH LETT said that the presence or absence of intussusception in Henoch's purpura was very important. He had reported a case in which intussusception had developed during the illness and was reduced by operation. 17 days later another intussusception occurred and the child died. He thought that the crucial feature to be relied upon was the presence of a sausage-shaped tumour and that there should be no operation where a tumour was not felt. He had operated upon 28 cases of intussusception, in all of which he felt a tumour either from the abdomen or per rectum. In two or three of them he could not feel it without an anæsthetic. Surgical operation in Henoch's purpura was a very serious matter and in some cases the patient had died of hæmorrhage from the wound. If he saw another case of undoubted intussusception with purpura he would be inclined to try injection before operation.—Dr. LANGMEAD said that a tumour might be present simulating intussusception but due to extravasation of blood, and Dr. SPRIGGS referred to another case showing this condition.—Dr. CAUTLEY thought that the term "Henoch's purpura" should be dropped, as the disease was simply purpura hæmorrhagica with abdominal symptoms, and Dr. PERNET agreed.

Mr. J. P. LOCKHART MUMMERY showed a case of Hyperplastic Tuberculosis of the Rectum in a boy, aged 10 years. There was no pain or straining but the bowels were loose, being opened as many as 20 times a day. There was no vomiting or wasting and the appetite was good. Large masses could be felt projecting in the rectum from all sides, irregular in surface and shape. With the sigmoidoscope several ulcers about a third of an inch in diameter were seen and had the appearance of tuberculous ulcerations. The whole of the mucosa of the rectum was red and swollen. The ulceration quickly cleared up as the result of daily irrigation with weak antiseptics.

Dr. CARPENTER showed a case of Scurvy in a boy, aged 16 months. He had been reared on cow's milk and barley-water for the first three months, and afterwards had been given bread-and-milk, &c. He was admitted to hospital with a history of two falls, and was found to have a bruise over the right eye and a hæmatoma of the scalp with a cranial fracture. After 12 days he was discharged as cured and continued in good health for six weeks when he was readmitted with a swelling in the left arm without any history of injury. The swelling extended from the shoulder on to the forearm. There were also marks of old hæmorrhages on the backs of both feet. The skiagram showed no fracture. He had improved very much on a suitable diet.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Beri-beri.

A MEETING of this society was held on April 16th, Sir PATRICK MANSON, the President, being in the chair.

Dr. W. LEONARD BRADDON (Selangor, Federated Malay States) communicated a paper on Beri-beri, which was read by Dr. T. S. KERR. The writer said that in British Malaya the European civil population shared with the native races all the possible factors of causation of disease; there was between them the difference only of food; the natives were rice eaters, the Europeans were not; the Europeans, with rare exception, never got beri-beri, the natives did. The Sikhs, Pathans, and Punjabis, of whom there were some 10,000 in the Straits Settlements and native States, whose customary diet was wheat flour, exhibited as a community an immunity from beri-beri as complete as that of Europeans; of 4237 hospital patients of that class, less than 1 per cent. were diagnosed as beri-beri, some of whom, as paupers, had been fed on rice. In Japan, where the natives (rice eaters) were attacked, the numerous colony of Europeans and Americans of every class, and even the Ainhos (non-rice eaters) escaped. If beri-beri, wherever occurring, was due to rice, then it was urged its incidence on rice eaters ought to be everywhere the same instead of as at present showing such violent contrasts, one rice-eating community being unaffected, another being exterminated. That assumed rice to be always the same, but that it certainly was not, and the facts which followed were evidence that among rice eaters beri-beri attacked only eaters of certain sorts of rice. For the Tamil the rice was prepared from grain which was boiled before the husk was removed (cured rice). The Chinese, on the other hand, never used cured rice. Both races were susceptible to beri-beri. Always and everywhere the uncured rice-eating community (the Chinese) suffered from beri-beri. The cured rice eaters (the Tamils) with equal invariability escaped. There was abundant evidence to show that among rice eaters those who consumed fresh village rice—e.g., the agricultural Malay, the Dyak—were exempt from beri-beri, so that among rice eaters beri-beri attacked only those who ate certain sorts; cured and fresh rice were innocuous. Cured rice, which did not produce beri-beri in its consumers, consisted of the whole grain from which only the husk had been removed, so that rice itself *qua* rice was not poisonous, and the factor in uncured rice which entailed beri-beri must therefore be some quality added to or lacking in the original grain. In uncured rice the fat and proteid content was reduced; moreover, the seed divested of its protective envelope readily decayed and was more easily attacked by various agents of decomposition. It was always more or less stale. Numerous observations proved that lack of fat was certainly not a cause of beri-beri; and although there seemed more evidence in the proteid starvation view propounded by Takaki, a survey of the published dietaries of the communities among whom beri-beri was severe furnished evidence that proteid if deficient in them was not so to such an extent that it could have been productive of disease. The presence of a poison in uncured rice explained all the phenomena of beri-beri; the disease being due to a poison present in variable proportion in the rice consumed, the effects will be proportionate to the quantity of noxious rice eaten, and the length of time during which it was eaten. In epidemics in which the diet had been improved, where it was claimed that the disease had been thereby checked, there had been, simultaneously with the addition of other articles, a reduction in the amount of rice. It was plain, therefore, that the toxic quality of the uncured rice which produced beri-beri was an added effect; either the grain itself became altered in its nature (poisonous proteins) or it became the seat of growth of agents (e.g., ferments, bacteria, fungi) which produced a poison of their own. In both cured and fresh rice the grain had been boiled or cooked almost at the same time as it was husked, uncured rices being boiled and eaten only long after they were husked. The difference between rice which was toxic and rice which was non-toxic was therefore a question of boiling early or boiling late. A time element was imported—implying change, a process of some kind, a growth in uncured rice for which time was required but which simple boiling of the grain immediately it was stripped of its envelope entirely prevented. There could be little doubt that the noxa was a living thing, but whether an enzyme or an epiphyte, who could say? From the observation that horses fed on unhusked rice became affected with a disease resembling beri-beri it was conjectured that the active agent was some epiphyte existing in or upon the envelope of the rice and able to invade it saprophytically under appropriate conditions when husked. It was specific to rice, as the use of no other cereal had been proved to entail beri-beri. The evidence, it was claimed, proved conclusively what from want of facts Van Dieren was not able to more than indicate as probable, and there had been demonstrated the fact that the change which rendered such rice poisonous might be avoided if, when it was necessary to store it unhusked, it were boiled before husking.

Mr. A. R. WELLINGTON (medical officer in Sarawak) communicated some notes on Beri-beri Outbreaks among Chinese, Dyaks, Malays, Javanese, and Tamils in the gaols and hospitals and in the mining and agricultural districts and communities of Sarawak. Some of the facts, he noted, would seem to indicate that beri-beri was infectious, others that it was due to food intoxication; in one case he considered that its disappearance was undoubtedly due to change of diet. He was unable to prove that bed bugs were carriers of beri-beri, but since the bed bugs in the general hospital at Kuching were got rid of no fresh cases had arisen there. As regards lice, he had no evidence to offer except in so far that beri-beri broke out in gaols and institutions where the inmates were subject to inspection and presumably therefore less lousy than the general population. With regard to rice, he asserted that beri-beri was unknown amongst the Dyaks, the natives of the interior, who husked their own "padi," yet those people if they came to an endemic area were just as apt to suffer as the Chinese. He instanced the case of a gaol in which the prisoners were fed on native newly husked rice and among whom no case of beri-beri had ever occurred; in Baram, too, they claimed to have ousted the disease by feeding people on fresh rice, not necessarily native rice, but Siam rice, which looked fresh. On the other hand, among the coolies at Brooketon coal mines beri-beri was at one time rampant, whereas now there was none, yet no change had been made in the rice used. Instances were cited by Mr. Wellington as cases of apparent infection, and as showing the difficulties of tracing beri-beri to rice intoxication he quoted many more instances. He then quoted possible instances of place infection or of infection conveyed from one individual to another, and gave details of an undoubted instance of the disappearance of beri-beri from Kuching jail following the use of freshly [illegible] nt. of [illegible] three [illegible] slight [illegible] as to be overlooked, in other cases fairly severe and akin to influenza and often diagnosed as such, but followed on the third or fourth day by numbness and weakness and confirmed as beri-beri by the subsequent history.

Dr. W. CARNEGIE BROWN said that in Italian ships in which the crews lived on rice and in which the sanitary conditions were bad beri-beri was unknown, but in Norwegian vessels in which the dietary was good, with but little rice, and the sanitary conditions were good beri-beri was very common. Beri-beri was a disease of association.

Brevet Lieutenant-Colonel W. B. LEISHMAN considered that perhaps rice would be found to play an important part in the causation of beri-beri.

Replying to Dr. J. L. MAXWELL, Dr. CARNEGIE BROWN stated that the husk was removed from the rice at the mill, but the rice was stored at the mill sometimes for five or six months before being husked.

Mr. JAMES CANTLIE said that it looked as if the long storage of the rice might have something to do with the question.

Dr. G. C. LOW observed that the cases of beri-beri in ships were identical with cases of beri-beri in the East.

Dr. T. S. KERR said that since orders had been given that the inmates of public institutions in the Straits Settlements should be fed on cured rice not one case of beri-beri had occurred in those institutions.

Dr. J. P. BRADLEY said that in the prison at Seychelles beri-beri was observed to break out when the prison was crowded.

The PRESIDENT mentioned that Tamils living on cured rice in Rangoon contracted beri-beri. Until the germ or the toxin of beri-beri was discovered, and until direct experiments could be carried out and the results watched, it would not be possible to decide the question.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Atmocausis.—Rotunda Hospital Reports.

A MEETING of this section was held on April 2nd, Mr. E. H. TWEEDY, the President, being in the chair.

Dr. R. D. PUREFOY showed a small Uterus removed for recurrent hæmorrhage from a patient, aged 50 years, the mother of some children. She had been curetted in the first instance and some thickened membrane had been removed. Some improvement was made, but the hæmorrhage recurred. Atmocausis was applied, but after another violent recurrence the uterus was removed. The specimen showed enormously thickened uterine walls and almost complete absence of endometrium.—A discussion followed on the value of atmocausis in the treatment of similar conditions, in which Dr. A. N. HOLMES, Dr. H. JELLETT, Sir W. J. SMYLY, Professor A. J. SMITH, and the PRESIDENT took part.

Mr. J. S. SHEILL exhibited an improved Material for Ligaturing the Umbilical Cord

Professor SMITH opened an adjourned discussion on the Obstetrical and Gynæcological Reports of the Rotunda Hospital. He said that there was little difference between the report and those of 12 years ago. Recent reports seemed to have become stereotyped. It was a most striking fact that the work done in the extern and intern departments was practically the same as regards results. Such a fact reflected great credit on all concerned and was an immense change from olden times, when it was safer to be confined outside a maternity hospital than inside it [illegible] was high in operative cases in [illegible] care was taken.—Sir WILLIAM [illegible] good thing that the report had assumed a stereotyped form, as it enabled them to make comparisons and to note advances such as the report showed. In 1886 there were four deaths out of 15 abdominal sections; in the present report there was one out of 10 times that number: that was a remarkable advance. He thought the report was the very best he had seen, both as to the matter it contained and the way in which it was brought out.—Dr. F. W. KIDD, after commenting on certain cases in the report, said that there were 235 abortions in the extern department and only 40 in the intern, although the total numbers attended were practically the same in each department. He thought that was due to women staying at home in preference to going to the institution. He observed that there were 3½ times more adherent placentas in the extern than in the intern departı [illegible] made to expel the placent [illegible] made to contract and [illegible] ident may have rushed [illegible] He thought the morbidity table served to emphasise the danger of the introduction of [illegible] —Mr. SHEILL said th [illegible] vomiting" and "eclar [illegible] that the urine of the patients contained albumin, but there was no mention of the output of urea or ammonia, which was considered to be of importance in diagnosing the severity of a case. He made a practice of estimating the output of urea on the appearance of the first sign or symptom of toxæmia and found it of great value. Also in pernicious vomiting, if the percentage of ammonia reached eight or ten of the total nitrogen excreted, then it was an indication for emptying the uterus.—After Dr. PUREFOY, Dr. HOLMES, Dr. T. NEILL, and Mr. TREVOR N. SMITH had discussed different aspects of the report, Dr. JELLETT said there were very few reports of any hospital of the kind that could produce the statistics shown in the tables of eclampsia and Wertheim's operation They stood out as important proofs of what could be done by careful treatment and successful operation. He thought there was nothing so important as keeping reports stereotyped for purposes of comparison, though not excluding fresh matter. He observed the omission of some tables which were formerly included, such as those on prolapse of the cord, post-partum hæmorrhage, and the sex of twins.—The MASTER OF THE ROTUNDA, in reply, said he made it his object to take up one or two fresh subjects in each report, and he had dealt with the treatment of eclampsia the previous year. His mortality was 11 per cent., as compared with 35 per cent. 20 years ago. He had not dealt with pubiotomy, as they had not had a case during the year. He dealt with it fully last year, when they had five cases. He preferred Cæsarean section as an easier and safer operation if he got the case in time. His indication for performing pubiotomy arose when he was sure he could not get a living child save by enlarging the pelvis. Ether was used in [illegible] of Cæsarean section that died. It was an extraordinar [illegible] t hæmorrhage. [illegible] mith was

also most thorough, and he points out that it is impossible to give a satisfactory account of the pathology at present, since although research has taught us the localisation of the process and how to explain it, it has not revealed its actual starting point or its nature. The article includes a special discussion of the treatment of tabes and is a most valuable account of the disease.

A useful and careful description of syringomyelia is given by Professor F. Schultze. The pathology and pathological anatomy are discussed in some detail. The same authority contributes the article on progressive muscular atrophy, in which the myopathies or muscular dystrophies are also considered, and the various forms which have been separated are regarded as varieties of the same affection. In regard to the spinal forms of progressive muscular atrophy, three varieties are described—viz., the infantile hereditary or Werding-Hoffmann form, the ordinary Aran Duchenne type, and amyotrophic lateral sclerosis or the Charcot form. The article also includes a description of the progressive neurotic muscular atrophy of Hoffmann. The account of neuritis and polyneuritis by Dr. R. Cassirer of Berlin contains a useful classification of the causes. The various forms of mononeuritis and polyneuritis are carefully differentiated and some good coloured plates are given of the pathological changes occurring in these conditions. Dr. L. Edinger of Frankfort-on-the-Main discusses the etiology of migraine and the various forms of headache. Professor Erb describes the characters of paralysis agitans, and while accepting the view that it is the result of a fine nutritive molecular disturbance principally localised in the motor apparatus, confesses that the origin of the disease is still mysterious. Dr. L. v. Frankl-Hochwart of Vienna contributes articles on athetosis, tetany of adults, and Thomsen's disease. He gives a highly interesting account of his own observations on the epidemico-endemic form of occupation tetany and the association of psychoses with it. Professor Th. Ziehen of Berlin, in an interesting and illuminating study of hysteria, gives some valuable and suggestive instructions in regard to treatment. His analysis and description of the protean symptoms of this condition are also helpful and clear. A valuable study of traumatic neuroses is given by Dr. P. Schuster of Berlin, and the various occupation neuroses are described by Dr. Cassirer.

The book as a whole is one which should be of real value to the practitioner as a work of reference in regard to diseases of the nervous system and their treatment.

The Third Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By ANDREW BALFOUR, M.D., B.Sc. Edin., F.R.C.P. Edin., D.P.H. Camb., Director. With 28 coloured plates, 51 reproductions of black and white drawings, 263 reproductions of photographs, and 19 maps and plans. London: Published by Baillière, Tindall, and Cox for the Department of Education, Soudan Government, Khartoum. 1908. Pp. 477. Price 21*s.* net.

THE third biennial report of the Wellcome Research Laboratories, Khartoum, continues the record of the valuable and interesting work described in previous reports. But the material which has become available and the scope of the investigations are year by year increasing greatly. The first report was contained in some 87 pages of text, with 61 plates, drawings, and plans; while that just issued comprises 477 pages, with no fewer than 361 illustrations of one or another kind. This is not all, for Dr. Balfour has issued a supplement of 251 pages of additional matter, to which we direct notice separately below. It is not surprising that the material to be reported upon has increased, since the functions of the Research Laboratories as formally set out are extremely far-reaching: they include the promotion of technical education; the study of tropical diseases by the most modern methods, particularly those maladies which afflict man and beast in the Soudan; the rendering of assistance to medical officers in civil and military hospitals, by laboratory investigations, in the diagnosis of disease; the giving of aid in medico-legal inquiries; the analysis of water and foodstuffs; the study of the disorders and pests which attack food and textile-producing plant life; and the undertaking of the assaying of agricultural, mineral, and other substances of importance in the industrial development of the Soudan. Dr. Balfour has made a new departure by including in the present report papers written by Soudan officials, members, for example, of the Egyptian Army Medical and Veterinary Services, and others who are not actually on the staff of the Research Laboratories.

The director of the laboratories is also medical officer of health of Khartoum, and in this capacity he has introduced into the report, under the title of "Sanitary Notes," a very complete description of the sanitary circumstances of that city, giving also a comparison between its present actual condition and that which obtained before the British occupation, illustrated by photographs and plans. Details are given of the water-supply, the conservancy methods, disposal of sewage, the state of slaughter-houses and markets, the milk-supply, and other matters which have to be supervised by the health department. Dr. Balfour points out incidentally the difficulties he meets with in enforcing health regulations, even with the help of the Egyptian policeman, who is, however, we learn, as far as sanitary matters are concerned, "a monument of stupidity," and who often aids and abets offenders "through the kindliness of his heart and the thickness of his head." Incorporated with these Sanitary Notes is an instructive paper on Dwelling-houses in the Tropics, with Special Reference to the Soudan, by Mr. W. H. McLean, lecturer on civil engineering in the Gordon College and municipal engineer for Khartoum. Dr. Balfour has to admit that with the increase of administrative work less time is left to him for the conduct of laboratory investigations. But notwithstanding this he has found time to contribute to the present report scientific articles on Trypanosomiasis in the Anglo-Egyptian Soudan; Hæmogregarine of the Jerboa, &c.; Piroplasmosis in the Soudan; Spirochætosis of Soudanese Fowls; and on Sleeping Sickness in the Bahr-el-Ghazal, to which are appended by Lieutenant R. G. Archibald, R.A.M.C., the pathologist and assistant bacteriologist of the laboratories, additional notes on that disease in Uganda. Other contributions are made on the subject of Kala-Azar in the Anglo-Egyptian Soudan, by Captain S. Lyle Cummins, R.A.M.C., of the Egyptian Medical Service, and by Bimbashi L. Bousfield, R.A.M.C., Egyptian Medical Corps, on Observations of Kala-Azar in Kassala Province. It deserves mention that the cases of kala-azar which came under observation were mostly traced to districts bordering on Abyssinia, where, as in the Soudan, many villages and towns are infested by bed-bugs which are suspected to be the agents in diffusing the disease.

It is with great regret that Dr. Balfour chronicles the death from kala-azar, contracted during his short period of service, of Dr. A. MacTier Pirrie, who was engaged in anthropometrical studies among some of the least known tribes in the wilder parts of the Soudan. His notes and the specimens and drawings which he had collected were submitted to Dr. David Waterston, lecturer on anatomy in the University of Edinburgh, who has been good enough to arrange them and to prepare them for publication under the title of "Report upon the Physical Characters of Some of the Nilotic Negroid Tribes," profusely illustrated by reproductions of photographs and drawings. Other notes on ethnographical specimens collected by the late Dr. Pirrie have been arranged for publication by Mr. D. J. Vallance, curator to the Royal Scottish Museum, Edinburgh.

A most interesting report is contributed by Dr. C. M. Wenyon, protozoologist to the London School of Tropical Medicine, who acted as travelling pathologist and protozoologist during 1907–08, and who made some valuable investigations on board the floating laboratory which was moved up and down the Nile and its tributaries as required. This novel laboratory was suggested by Dr. Balfour, and Mr. H. S. Wellcome generously supplied the equipment. Opportunities were taken by this means to investigate locally certain diseases, including dysentery and guinea worm, and among other things trypanosomiasis in certain animals, including Nile fishes. This report is illustrated by coloured plates. Dr. Wenyon also collected a number of specimens of parasitic worms which were handed on his return to this country to Dr. R. T. Leiper, helminthologist to the London School of Tropical Medicine, who prepared an account of them for publication in the report of the Research Laboratories. Dr. Wenyon, in addition, collected a number of specimens of reptiles at the different stations in the Upper Nile and Bahr-el-Ghazal provinces, as well as a number of poisonous snakes. These collections were examined and reported upon by Dr. Franz Werner, assistant in the First Zoological Institute of the University of Vienna. A most useful report on economic entomology is contributed by Mr. Harold H. King, member of the Association of Economic Biologists, in which he deals with animals injurious to man and animals; those injurious to farm and garden crops; those injurious to trees and shrubs; and lastly, those injurious to stored goods and timber. He has also something to say on fungoid pests and the like. His paper is profusely illustrated by coloured plates, and we can quite understand how it came about that from his conspicuous knowledge of entomology Mr. King was named by the Soudanese "the father of flies." "New Mosquitoes from the Soudan, and List and Synoptic Table of all Soudanese Species," illustrated by many drawings, form the subject of a contribution by Fred. V. Theobald, vice-principal and zoologist at the South-Eastern Agricultural College, Wye. A historical paper on the healing art as practised by the dervishes in the Soudan during the rule of the Madhi and Khalifa appears from the pen of El Bimbashi Hassan Effendi Zeki, of the Soudan Medical Department, medical officer to the Gordon Memorial College. Dr. Zeki, it may be mentioned, occupied the position of medical adviser to the Khalifa in the troublous days preceding the reconquest of the Soudan by the British and Egyptian troops. The native methods of treatment of diseases in Kassala and neighbourhood are discussed by Captain Bousfield, and this paper is supplemented by valuable additional notes contributed by Sir Rudolf Slatin. Medical practices and superstitions amongst the people of Khordofan, their treatment of disease, and their chief drugs, instruments, and appliances in common use are commented upon by Captain R. G. Anderson, R.A.M.C., Egyptian Medical Corps. This paper is illustrated by drawings and photographs and is extremely interesting. The volume concludes with a report of the chemical section of the Research Laboratories by Dr. William Beam, F.I.C., the chief chemist, who was assisted in his important work by Mr. J. A. Godson and by Mr. E. S. Edie, B.Sc., Carnegie research scholar in chemistry 1907–08, who carried out a special research on the chemistry and bacteriology of Soudan gum-arabic.

In the preparation of his third report Dr. Balfour has had to encounter unusual difficulties, the most serious of which was a disastrous fire in May, 1908. In this conflagration a large portion of the Research Laboratories at Khartoum were destroyed along with many specimens and preparations, books, papers, and records which had taken years to collect. Much of the equipment of the laboratories was destroyed or damaged. Thanks in a great measure to the prompt and generous help given by Mr. Wellcome the laboratories were quickly refitted and the work was soon carried on again as before.

Supplement to the Third Report of the Wellcome Research Laboratories, Khartoum: a Review of Some of the More Recent Advances in Tropical Medicine. By A. BALFOUR, M.D. Edin., &c., and R. G. ARCHIBALD, M.B. Edin., R.A.M.C. London: Published by Baillière, Tindall, and Cox for the Department of Education, Soudan Government. 1908. Pp. 251. Price 10*s.* 6*d.* net.

THIS supplement to the biennial report is modestly termed by Dr. Balfour a "review." It is intended to help medical and veterinary officers stationed in the Soudan, especially those in out-stations, by keeping them in touch with current literature. It is also intended to serve as a guide to new books and papers dealing with recent discoveries and advances in our knowledge of tropical and veterinary medicine, bacteriology, and hygiene, more particularly where these have a bearing on the medical, sanitary, and veterinary work in the Anglo-Egyptian Soudan. The subjects dealt with in this "Review," some 89 in number, are arranged alphabetically so that reference to them is easy. They treat mostly of tropical diseases, but there are special articles on various subjects, such as air, blood, climate, clothing, dust, disinfection, filters, flies, food, ice, milk, mosquitoes, sewage, water, and vaccination. The "Review," though intended primarily for the use of officials in the Soudan, cannot fail to be of great service to many workers in other tropical countries. It will also be of value to those who are studying tropical medicine and preparing for examination, particularly as it is provided with a serviceable detailed index which will greatly assist the reader who seeks for information on any branch of a given subject. We congratulate Dr. Balfour and Lieutenant Archibald on the production of this excellent piece of useful work.

Naval Warfare: Its Historical Development from the Age of the Great Geographical Discoveries to the Present Time. By Baron CURT VON MALTZAHN, Vice-Admiral (retired). Translated from the German by JOHN COMBE MILLER. London: Longmans, Green, and Co. 1908. Pp. 152. Price 2*s.* net.

THIS book consists of a series of lectures on the Historical Development of Naval Warfare, delivered at Hamburg by Baron Curt von Maltzahn, a Vice-Admiral of the German Imperial Navy. They were afterwards published in book form for the enlightenment of the German nation, and they urge the supreme need of maritime knowledge and development; and for this very reason the book has a great general significance and is full of suggestion to all Britons, to whom the sea and all that pertains to it are of such vital importance.

Admiral von Maltzahn, in discussing his subject, does not allude to any matters of medical or sanitary interest from the strictly professional point of view. He defines war as "a conflict of interests which is solved in blood," and just as war emerges out of the conditions of peace so it also tends back towards peace again, its aim being to compel peace on the victor's own conditions. He regrets that naval matters before the formation of the German Empire had not their proper significance to the German people and were not rightly understood because the exploits of their own armies, which liberated the fatherland from the yoke of the foreigner, loomed larger in their eyes. Naval warfare, according to his view, has hitherto been waged on two different methods; in one case the sea is seized by [illegible] "thoroughfare of [illegible] and secondly, the sea is left open and descents are made on the enemy's sea-borne trade. Besides these two methods there are others which partake of the nature of both—viz., doing damage along the enemy's coasts and, if possible, invasions by land forces. Colonies and over-sea trade may also be made to suffer. This sums up what is apparently the writer's view of German strategy and German tactics (an insight of which is of national interest to us at present), and it is based on a pithy historical review of naval wars (chiefly British victories being quoted) from 1500 to the late Russo-Japanese war. In the events of 1805 prior to the battle of Trafalgar it is pointed out suggestively that the British blockade in front of the French harbours was aimed at keeping the different sections of the French fleet apart and that this object was achieved. Attention is also drawn to the fact that the "English with their practicality and strong dislike of theorising" held out in modern times longest against naval manœuvres in peace time, until it was realised how closely such manœuvres could be made to imitate real warfare, when "the rich resources and the practical sense of seamanship possessed by the English enabled them to redeem the time they had lost, and at the present moment England in this regard stands once again in the foremost place." Contrast is made between the *matériel* and *personnel* of the British and German fleets. "If a short time ago it could be said of England that the strength of her naval equipment consisted rather in the quantity and quality of her ships than in any systematic preparedness for war from the strategical and tactical standpoints, we [Germany], on the contrary, have always been better off in the matter of technical than of [illegible] the importance of the [illegible] of land forces useless [illegible] cut, Nelson's victory at Aboukir Bay is quoted, explaining that Napoleon's army in Egypt was cut off from Europe, and showing how a similar catastrophe would have befallen the Japanese army in Manchuria had Rozhdestvensky's fleet triumphed and defeated the Japanese navy. The weak points in the armour of Germany are hinted at, one being "blockade of German ports," for "not simply the coasts but the whole country would suffer ... . it would knock at the inland office of the merchant, it would hammer at the gates of the factories in the great industrial centres in the heart of the country, [illegible] working [illegible] are more [illegible] fear from [illegible] England's hands."

We may be considered to have given a book of no especial medical interest undue prominence when so much excellent medical literature calls for attention, but the subject is of the utmost importance to every Briton, for the safety of our island home depends on our navy. The book is well translated and most readable; and to the translator, Mr. J. O. Miller, a debt of gratitude is due for making it available.

LIBRARY TABLE.

The Care and Nursing of the Insane. By PERCY J. BAILY, M.B., C.M. Edin. London: The Scientific Press, Limited. 1908. Pp 270. Price 2*s.* 6*d.* net —This little book opens with a clear, succinct, and sufficient description of the anatomy and physiology of the human body. As a rule in this class of work anatomical details are over elaborated, but in the one before us we feel that the author has realised during his experience as lecturer that it is impossible to expect the average member of the average class to absorb more than the broadest anatomical facts. In the latter part of the book there are wholly admirable and minute directions as to the toilet of the sick, their feeding and treatment, and it is concluded with an excellent account of the most common symptoms, while most wisely no unnecessary attempt is made to enable the nurse to form his or her own diagnosis. We can with confidence recommend the book to nurses and to lecturers to nurses.

Golden Rules of Anæsthesia. By R J. PROBYN-WILLIAMS, M.D. Durh. Golden Rule Series, No. XIV. Bristol: John Wright and Sons. Third edition, revised. 1908 —The appearance of a third edition of this little book is proof enough of its suitability to the ends which it desires to meet. It contains in fact in condensed language and small compass most of the leading facts and principles which a student should incorporate into his knowledge before he regards himself as familiar with the subject of anæsthetics. Naturally, in a tiny work like this there are omissions, and we should have liked to see some mention of so important, if still debateable, a question as delayed chloroform poisoning. Moreover, the student who uses a work of this kind must of course realise that the writer takes for granted in his readers a full knowledge of the physiology of the subject. In the paragraphs dealing with chloroform there should, we think, be introduced some account of regulating inhalers, and in those discussing ether an account of the simplest and in some ways the best of all ways of giving ether, viz., by the open method, ought to be included.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. II., No 6. London: Longmans, Green, and Co.—The outstanding feature of this liberal number is the continued report of the discussion on ulcerative colitis on Feb. 10th, to which some 70 pages are devoted. They include a summary of statistics of the disease from the records of nine London hospitals and are a valuable contribution to its literature. The report includes remarks by Sir Patrick Manson, Dr. T. Claye Shaw, Dr. Sidney P. Phillips, Mr. W. G. Spencer, Dr. Norman Dalton, Mr. J P. Lockhart Mummery, Dr. Bertrand Dawson, Dr. J. P. Zum Busch, Dr. H D McCulloch, and Sir William H. Allchin. In the Surgical Section Dr. J. Kay Jamieson and Mr. J. F. Dobson publish a painstaking research into the lymphatics of the colon, approaching their subject from both the anatomical and pathological standpoints, and Mr. R. J. Godlee writes on the Torus Palatinus, a median bony ridge in the hard palate occurring in certain skulls. The report of the Anæsthetics Section is occupied with the latter part of the discussion on the proposed Anæsthetics Bill, which has received much attention in our columns. The Clinical, Dermatological, and Laryngological Sections report a series of cases too numerous to mention, amongst which notes upon elephantiasis treated by lymphangioplasty, by Mr. W. S. Handley, and upon a case of anæsthetic leprosy, by Dr. H. P. Hawkins, are of especial interest. The Neurological Section contains an account of the remarkable results obtained by the alcohol injection treatment of neuralgia and spasm contributed by Dr. Wilfred Harris. To the Obstetrical and Gynæcological Section Dr. Frederic J. McCann contributes a paper on Primary Sarcoma of the Fallopian Tubes, a rare form of tumour. In the Odontological Section is an instructive communication from Mr. K. W. Goadby on the general results of the special rules in force in match factories, in which he concludes that "a marked decrease has taken place in the amount of industrial phosphorus poisoning concomitantly with an improvement in the dental condition of the workers in the various factories." In the Otological Section Mr. Sydney R. Scott contributes a well-illustrated description of some sections of the human cochlea through the organ of Corti, showing a beaded nerve fibril traversing the tunnel of Corti, and cell fibrillæ projecting from the hair-cells. The Therapeutical and Pharmacological Section concludes the number, and under this heading the constant swinging of the medical pendulum is to be felt in Dr. E. I. Spriggs's paper on the treatment of gastric ulcer by immediate feeding, in which he compares the Lenhartz dietary to the treatment by saline and nutrient enemata followed by a graduated milk diet somewhat to the advantage of the former method.

Le Larynx, l'Oreille, et le Nez. Jan.-Feb., 1909. Paris: Maloine. Price 75 centimes.—This number contains an article of much technical value on direct laryngoscopy which will be read with interest by all who wish to get the views of other observers upon the latest method of dealing with diseased and other abnormal conditions of the upper air passages; beyond this there is nothing novel in this issue.

Reports and Analytical Records FROM THE LANCET LABORATORY.

PLASMON.

(INTERNATIONAL PLASMON, LIMITED, 66A, FARRINGDON-STREET, LONDON, E.C.)

WE reported upon plasmon in these columns nearly nine years ago, when we set before our readers the ordinary results of a chemical analysis. Our attention has recently been drawn to the fact that plasmon, since it is pure milk protein, contains phosphorus associated with the proteins—that is to say, in an organic form. It is well known that ash-free casein contains phosphorus as apparently part and parcel of its molecule, the quantity present being estimated as 0·85 per cent. Casein free from salts would not yield a phosphatic residue on ignition, but when associated with mineral salts there is little doubt that part of the organic phosphorus forms phosphates which are found in the ash on igniting the substance. The importance of phosphorus in organic association has lately been emphasised, and preparations like lecithin and the glycero-phosphates have been introduced into medicine as of value in neurasthenia and nervous disorders generally. There is reason for believing that organic phosphorus compounds of an allied nature exist in plasmon. According to our analysis the total phosphorus calculated as phosphoric acid in plasmon acting on it with nitric acid is 2·88 per cent., the amount found in the ash gives 2·24 per cent., while the amount extracted from plasmon by weak acid was 1·42 per cent. The organic phosphorus, therefore, lies between 2·88 and 1·42 per cent.—that is to say, to about 1·46 per cent., which is the amount found in terms of phosphoric acid in pure milk proteid. Milk proteid is, in fact, distinguished from other proteids by containing phosphorus, and it is satisfactory to observe that this element is not eliminated in plasmon.

COFFEE FREED FROM CAFFEINE.

(THE LIFEBELT COFFEE CO., 71, EASTCHEAP, LONDON, E.C.)

Caffeine is generally looked upon as one of the most important constituents of coffee, since, like alcohol, it is a stimulant, but differs from that substance inasmuch as its effects are exerted upon the central nervous system more than upon the heart. Thus coffee drinking is well known to remove sense of fatigue and in some cases produces sleeplessness. Coffee, therefore, has a definite physiological action, but in certain cases this action may be a harmful one. If it is proved that caffeine is responsible for the harmful effects of coffee the caffeine-freed article should be an introduction of some importance. We have carefully examined the sample submitted to us and found that while it preserved the fragrance and aroma of good coffee yet it contained only 0·16 per cent. of caffeine. Ordinary coffee contains, on an average, after roasting, about 1·0 per cent. of alkaloid, so that the above reduction amounts to about 84 per cent. of the total alkaloid. It is claimed that patients suffering from nervous affections or heart affections, who exhibit, in fact, an idiosyncrasy to ordinary coffee, not only take this coffee without harm but with benefit. The subject is an interesting one.

LACTIC TABLETS.

(ARTHUR H. COX AND CO., BRIGHTON.)

The statement that these tablets contain a culture of vigorous strains of the lactic acid bacillus was borne out in some experiments we made with them on milk. One tablet, after being crushed to powder, was placed in a little warm milk and the fixed acidity from time to time determined. After 24 hours the original acidity had doubled, and after 36 hours it had nearly trebled. The tablets are therefore useful for the anti-putrefactive treatment of the digestive intestinal tract.

DIGALEN.

THE HOFFMANN LA ROCHE CHEMICAL WORKS, LIMITED, 7 AND 8, IDOL-LANE, LONDON, E.C.)

This is a clear, colourless, sterile solution containing the active principle of digitalis folia. It is claimed that it has a certainty of action, admits of exact dosage, avoids gastric troubles, produces no cumulative effect, while its administration gains a prompt physiological response. These claims are supported by a number of excerpts from German medical literature published in a brochure issued by the above firm. The preparation is due to Professor Cloetta, who has succeeded, he states, in isolating from the leaves an amorphous digitoxin which is soluble in water. Each cubic centimetre of the solution corresponds to 0·3 milligramme of the amorphous digitoxin. The solution keeps well, being preserved with glycerin. It is further claimed that the hypodermic injection of digalen causes no irritation.

COGNAC BRANDY (FLOQUET FILS).

(FRANCIS GREEN AND CO., OCEAN HOUSE, 24 AND 25, GREAT TOWER-STREET, LONDON, E.C.)

We believe this brandy to be correctly described, both in regard to its origin and to its age. It presents the attractive characteristics of an old (21 years) liqueur Cognac brandy. As will be seen from the analysis it contains a relatively rich proportion of ethers. The analysis was as follows, the results being expressed in parts per 100,000 parts of alcohol present: volatile acidity, reckoned as acetic acid, 72; aldehydes, 40; furfural, 2; ethers, reckoned as ethyl acetate, 134; and higher alcohols, 136. These figures coincide very closely with those obtained with genuine old Cognac brandy. The alcohol amounted to 49·81 per cent. by volume, the extractives to 0·95 per cent., and the mineral matter to 0·02 per cent. This brandy has a smooth, refined flavour and is suitable for medical requirements.

BOTTLED FRUITS.

(THE BROUGHTON NURSERIES, WICKFORD, ESSEX.)

Three preparations were examined—namely, apples, blackberries, and tomatoes—and in no instance was any metallic contamination discovered nor were any objectionable preservatives found. The preparations are, in fact, sterilised and subsequently placed *in vacuo* in the bottle, which is provided with a lid forced on a rubber ring by atmospheric pressure. The fruits were in a quite sound condition and were satisfactory to the taste.

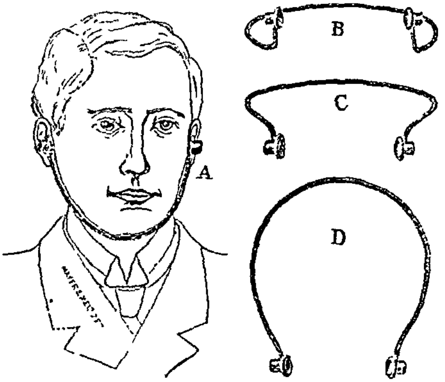
BURMESE AND CAROLINA RICE.

A correspondent in Rangoon recently asked us if we would submit to analysis a sample of Burmese rice, as prepared and eaten by the natives, with the view of deciding whether it showed a greater nutritious value than the Carolina rice usually sold by grocers in London. Our correspondent states that by the process which rice undergoes before it is sold in England it is deprived of part of its valuable constituents, the nitrogenous envelope, he adds, being polished off. According to the results of our analysis we can lend little support to this contention, for the following were the results:—Burmese rice: moisture, 15·70 per cent.; protein, 9·96 per cent.; starch, 74·04 per cent.; and mineral matter, 0·30 per cent. Carolina rice: moisture, 15·0 per cent.; protein, 10·14 per cent.; and starch, 74·86 per cent. The only appreciable difference between these results is that the Burmese sample contained a distinct quantity of mineral salts, while the Carolina sample yielded practically nothing on ignition. The starch and protein in both samples were practically identical in amount.

New Inventions.

A TRAGUS TRUSS OR EXTERNAL EAR PRESS.

THE external spring ear press or ear truss has been devised by me *to exclude or modify moderate noise sounds.* It possesses the great advantages that it does not disturb the ear, is clean to wear, and is easily put on and off. Great or bone convection sounds cannot be stopped by such a pressure instrument; indeed, for partly deaf people and using bone conduction or audiphone apparatus it would improve the effect through intercepting extraneous sounds. The spring ear press therefore should be used chiefly as an indoor instrument, and in conjunction with double or closed windows or any other quietening aids. The range of relief in this way from many disturbing sounds will be considerable. If used out of doors it will still account for at least the shutting off of distant noises, but not for all close noises. It will also be useful for producing sleep, especially when slight noises distract susceptible people and cause them to suffer in so exhausting a way. It sometimes stops the whirring noise of arterial high tension, in its turn partly a product of noise strain through afferent and tension results. Such noise becomes intolerable on laying the ear to the pillow or placing the head in any resting and dependent position. To wear the spring ear press the bow, which is rubber covered, fits under the chin in the case of the standard pattern A; behind the neck and below the ear in pattern B; or behind the head and above the ear in pattern C; and above the head in pattern D; the pads press on the tragus over each external meatus of the ears, and by pressure the spring and pads close the ear-conducting by-ways. The standard or chin shape, A, can be made in three ordinary sizes. The other three shapes, behind and above the head, may be preferred by some as being more easily worn or less noticeable; but these latter ones should be measured or fitted from e to ear.



The instruments have been made, according to my design by Messrs. Mayer and Meltzer, Great Portland-stree London, W.

H. ELLIOT-BLAKE, M.R.C.S. Eng.,
L.R.C.P. Lond., L.S.A.

Bognor.

APPARATUS FOR STRETCHING THE LIGAMENTS THE SHOULDER JOINTS.

THE accompanying illustration represents an apparatus f the use of golfers and cricketers in the gymnasium of t *Bournemouth Hydropathic for stretching the ligaments of t* shoulder joints. It may interest surgeons who are in sear of an apparatus that can certainly increase the range movements in these joints when they have been limited injury or disease. The apparatus consists *of*: 1. A whe four feet in diameter, fixed on a suitable stand which can made to revolve in a vertical plane. The movements m be produced by hand, pedal, or otherwise. To one spoke sliding clutch is attached with which is connected stirrup-shaped hand-piece. 2. A chair, consisting of a se capable of moving up and down by means of a vertic screw-support placed centrally. The back of the cha consists of a T-shaped structure, the vertical limb of whi fits into brackets attached to the seat, and can be raised lowered to suit the length of the back of the athlete usi the apparatus. A belt is fixed to the stem for encircling th *waist of the sitter.* To each end of the cross-piece a be is fixed for encircling the shoulders. The sitter, whe securely strapped to the chair, has the movements his spinal column limited to a minimum, and th shoulder-blades are practically immobile when the shoulde straps are securely fastened. The sitter, with his mesia plane parallel to that of the wheel and a little further tha an arm's length from it, grasps the stirrup-shaped handle which is at first attached *near the centre of the wheel.* O bringing the wheel into motion by the operator's hand or th pedal, the hand of the sitter is circumducted through a sma circle at first. The circle of circumduction is gradually increased by shifting the clutch towards the rim. The seat rotate on a platform, so that, without unfastening the sitter, hi other arm can be subjected to *similar exercise.*

The apparatus at work.

The Bournemouth Hydropathic Company will, we under [illegible] almost *net cost to any purely* [illegible] gathered by the above [illegible] many places, but we [illegible] use. Great mechanical [illegible] he various manœuvres, and we feel strongly that it should only be employed in cases where its need is certified by a medical man, and more, where the range of movements can be absolutely arranged by the surgeon and the results carefully watched. *Otherwise* the consequences might easily be very serious. It is especially important that it should not be employed in cases of stiffness of the shoulder resulting from tuberculosis, for in these the affection is often merely latent and such forced movements as might be [illegible] machine would almost certainly

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1909.

Treatment of Tuberculosis at Sea.

WE have received from Dr. A. N. J. HANEDOES of Vaassen, Holland, an interesting and suggestive communication dealing with the subject of the treatment of tuberculosis at sea. The plan of sending patients suffering from pulmonary tuberculosis on a sea voyage is no new one and some years ago was adopted more frequently than it is at the present time. The reason for this is simple; theoretically the effect of sea air should be most favourable on sufferers from tuberculosis, but hitherto the conditions of life encountered on board ship have outweighed the benefits that might be obtained if the cabin accommodation, diet, and other arrangements could be especially adapted for invalids. Dr. HANEDOES rightly draws attention to the characteristics of ocean air. It is absolutely free from dust and bacteria. The ozone it contains is probably also of therapeutic value, although, as far as we are aware, accurate and detailed observations on this point are wanting. Further—a matter of particular importance to those afflicted with pulmonary tuberculosis—a warm, equable climate with a sufficient amount of humidity can be assured. The physiological effect of sea air is also seen in its sedative action on the nervous system, and the aseptic condition of the air acts beneficially both on the air passages and the system at large. The salt that is present in larger proportion than in inland air appears to render the expectoration less viscid without injuring the mucous lining of the air passages. Dr. HANEDOES also maintains that owing to its greater density the physiological effects of sea air may be compared to those obtained in a pneumatic cabinet: the respiration is slackened and rendered deeper. Full inspiration is certainly of benefit in pulmonary diseases, and he further states that the "unconscious and continually deepened respirations unfold and strengthen the lungs much more than is obtainable on shore by gymnastics and walking." In expressing this opinion, we believe that Dr. HANEDOES only states a portion of the truth. The deep respiration brought about by "gymnastics and walking" is only one of the beneficial effects produced by these measures. Probably the chief result of active exercise is to bring about auto-inoculation, by means of which the protective forces of the body are brought into action, and owing to the increase of the opsonins the phagocytic power of the white corpuscles is increased. To this matter, however, we shall again refer. Other influences of sea air mentioned by Dr. HANEDOES are the general tonic action which it exerts and the increase of appetite which generally follows. "A delicious feeling of corporal and mental animation," he says, is experienced, and the desire for more food is naturally of advantage to tuberculous subjects.

Such being undoubtedly the beneficial effects of sea air, what are the drawbacks to sending patients on sea voyages? The first that suggests itself is the want of suitable accommodation on the ordinary ocean-going vessels. Although in recent years the cabins on board the large steamers have been greatly improved, nevertheless, on an ordinary voyage, there must be occasions, sometimes considerably prolonged, during which patients will be confined to their cabins, such as the continuance of inclement weather. Further, on long voyages, great variations of temperature are experienced and the dietary is of necessity not always in accordance with the needs of invalids, although every care that is possible is usually taken in this respect in large steamers intended for passenger traffic. Finally, but not least, sea-sickness is a condition that must be seriously considered in advising a tuberculous invalid to take a long sea voyage. It is obvious, then, that such objections as the above may well make the physician hesitate before recommending a patient to adopt this therapeutic measure. Dr. HANEDOES, however, makes proposals which, although not being altogether novel, yet are an advance on other plans which have been hitherto suggested. He recommends the formation of a floating sanatorium in the shape of a large sailing vessel, provided with an auxiliary screw, which would be useful in entering or leaving harbours, or in the case of calms. The ship would be especially fitted for the accommodation of invalids. Such a plan has been made before, but Dr. HANEDOES'S special point is the nature of the cruise. He rightly insists that the ship would have to sail according to a fixed arrangement, whereby season, temperature, degree of moisture of the air, qualities of the harbours to be visited, and the calmness of the sea must be all taken into account. The duration of the voyage would have to be about three months, and he suggests as the most suitable district for the cruise the neighbourhood of Madeira in the course of the north-east trade winds. There the desired conditions would be most closely fulfilled. The sea is calm for months and the temperature equable. What could be more enjoyable, he asks, to those fond of the sea than a voyage to Lisbon, then a cruise in the vicinity of Madeira and the Canary Islands, with occasional visits ashore, and calls at Cadiz and perhaps Havre on the homeward voyage? No far-distant destination being in view, the land could be kept in sight for a considerable time, shelter might be easily sought should unfavourable weather ensue, and fresh provisions could be constantly provided. Weariness and the constant confinement on board ship inseparable from a long ocean voyage would be avoided, whilst the maximum therapeutical effects could be produced.

The important question next arises, for what class of patients would this treatment be most applicable? For certain cases of tuberculosis of joints, when active exercise can only be indulged in to a limited extent, we believe that a voyage of the nature suggested would prove most beneficial. For young subjects with tuberculous glands, when sufficient active exercise could be obtained in the limited space available on the deck of a ship with occasional runs ashore, such a course might also be well adopted. With pulmonary tuberculosis, however, and when the patient is able to take a good deal of exercise or to perform manual labour, the question is not so simple. The results of auto-inoculation produced by "graduated labour" are very encouraging, and on a ship "labour" of the required kind would be difficult to arrange and control. For individuals in the early stage of the disease, we think that treatment on land under suitable supervision is certainly preferable. The best results of active exercise and labour are, however, only obtainable in persons of fairly good physique. There are numerous patients, who, from various causes, do not respond well to graduated labour; auto-inoculation cannot always be satisfactorily regulated. In others bronchial catarrh is an impedient to modern sanatorium treatment. For such cases a voyage of the nature suggested by Dr. HANEDOES might well be tried, and we believe that he has performed good service by putting forward his scheme, which we should like to see brought to a practical issue, provided that all the requirements mentioned above can be procured.

The Great Importance of Small Things.

OUR excellent contemporary *Punch*—and in our opinion the philosopher of Fleet-street has never been better worth reading and marking than now—has lately and genially called us to account as alarmists, and we are allowed to guess that the reason is that we have endeavoured from time to time to give publicity to fragments of knowledge of various kinds, for most of which, as for truths of every other description, it is probable that some useful application may one day be found. We are quite accustomed to the accusation that it is our grim pleasure to make the public flesh creep, but we hope that our thoughtful readers credit us with a worthier motive than delight in popular scares. The history of science teems with illustrations showing that no truth is either insignificant or incapable of becoming a starting point for further advances, and in our own day the importance of the infinitely little is constantly forced more and more upon our attention. When the great discovery was first promulgated that intermittent and yellow fevers were communicated to man by mosquito bites, scores of sciolists, globe trotters, and others, communicated to newspapers their several varieties of ignorance "Common Sense," who did not know the difference between typhoid fever and "yellow jack," had lived in countries where there were no "mosquitoes" and where "fever" was abundant and deadly; while "An Old Traveller," who did not know the difference between an anopheles and a stegomyia or between either of them and a culex, had been where "mosquitoes" were abundant but where "fever" was unknown. A discovery calculated to save millions of lives was looked upon as a fitting subject for the indignant remonstrances of the ignorant, chiefly, as far as we can see, because a gnat is such a common little thing that to suggest it as the medium for the dissemination of an appalling amount of deaths and of physical misery and incompetence partakes of the nature of a medical scare. An employé of a railway and dock company by calling the attention of the sanitary authorities recently to the occurrence on premises under his eye of certain dead rats may have saved us from a little epidemic of plague—we say "little" because our preventive system is so good that tropical diseases never get any firm footing within our gates. If this work had been epitomised under a paragraph headed "Fleas and Pestilence" we can imagine "Paterfamilias" summing up the story in a letter to the press as foolishly alarmist.

In another column a correspondent deals in an amusing manner with the questions propounded through the pen of "Paterfamilias" by *Punch* to us, and shows that under some of them, at any rate, ridiculous as they are, serious medical issues might well be discussed. We should perhaps be thought to be dealing too seriously with the matter if we followed up the different points on the lines wittily suggested by "F.R.C.S.," but we wish it to be understood that our aim is to call attention to real dangers which the ignorant or the frivolous are apt to overlook, and which in many cases merit more consideration than they commonly receive. The questions in *Punch* were, for example, suggested by a paragraph in THE LANCET on the poisonous nature of honeysuckle, and all who know the propensity of children to pluck and eat berries of tempting appearance, and the many instances of serious or fatal poisoning to which this propensity has led, will feel it to be desirable that publicity should be given to the fact that a plant with a name suggestive of sweetness may become a source of real danger. We wish it to be understood that we are by no means dealers in popular scares, and that the dangers to which we from time to time direct the attention of our readers are real ones. They may sometimes be small, and if so we do not attempt to exaggerate them. Knowledge of the channels through which disease finds access to the human body is daily increasing in the medical profession, and conditions which a few years ago would have been thought of only as annoying (bugs in hired lodgings, for example) are now properly regarded as possible sources of serious danger. Of the cases of indisposition to which a busy family practitioner is daily called, there are too few in which he can determine, with any approach to scientific certainty, the immediate cause of the ailment for which he is asked to provide a cure, and this because the patient and his family cannot tell him a succinct story. It is true that the patient will usually have no doubt upon the point, and will say at once how and when he "took cold," or what it was that "disagreed with him." His beliefs on the subject, as every medical man knows, are usually mere delusions, which it is useless to spend time in combating. We are coming more and more to regard a high standard of public health as a matter of national concern, and to realise that upon its maintenance may seriously depend the fitness of the coming generation to "speak with the enemy in the gate." In these circumstances it does not become us to neglect dangers because they may appear to be trivial, and while we recognise that the reproof of *Punch* was as kindly as possible, we must continue with dull seriousness to protest that we write in earnest and not with irresponsible gaiety.

The Resuscitation of the Apparently Drowned.

The Hunterian lectures delivered every year at the Royal College of Surgeons of England are always of great value, for they represent the latest opinion on matters of current surgical importance. Of the many recent Hunterian lectures we do not remember any of more interest than those delivered during the past month by Professor Arthur Keith on the mechanism underlying the various methods of artificial respiration.[1] From time immemorial various artifices have been employed to resuscitate those who have been immersed in water for a short period and have been apparently drowned. In superstitious ages the natural spontaneous wish to revive a drowned man was restrained by the tradition that a man rescued from drowning was destined to bring ill-luck to his rescuer, and though this superstition survives, we believe, in some parts of the country it has little influence in preventing the onlookers of a drowning accident from doing their utmost to revive the unfortunate victim. Zeal, however, generally outruns knowledge, and the dim recollections of methods of resuscitation are employed with much misdirected energy and probably with harmful results.

Dr. Keith took as his starting point the year 1774, when the Royal Humane Society was founded by Dr. William Hawes, and he reviewed all the devices for reviving the apparently drowned which have been in use or recommended from that day to this. It is a disquieting fact to learn that practically all the methods advised by the society in its early years have been discarded and condemned since; for the thought cannot fail to arise that our most cherished modern methods may in their turn be rejected by those that come after us. Stimulants to the nose and skin, bleeding, emetics, and the fumigation of the large intestine with tobacco smoke, all these were looked upon as valuable methods of reviving the drowned, but now they are unknown. Warmth and friction of the skin still survive and are of definite value, and especially useful is warmth. The only method of artificial respiration that was then known was direct inflation from the operator's mouth, and though this was discarded later by the society many recoveries were ascribed to its use, and it is probably by no means useless. As these lectures were given under the ægis of John Hunter it is interesting to note that at Dr. Hawes's request John Hunter supplied suggestions for the restoration of the apparently drowned, wherein he gave the first place to artificial respiration carried out by means of a double chambered bellows which he invented for the purpose, one chamber being used for filling and the other for emptying the lungs. He proved the efficacy of the bellows on dogs, and at the same time he suggested that oxygen, which had been discovered by Priestly only two years before, might be more potent than air. Dr. Keith did not have time to consider fully the whole question of the resuscitation of the drowned, so he dealt mainly with the question of the consideration of the best method of introducing air into the lungs. In cases of drowning it is now acknowledged that water does enter the lungs, though until quite recently this fact was denied. In one case a dog in drowning received into its lungs more than 700 cubic centimetres of water; and one part of the problem of resuscitation is the removal of this water from the lungs. Some of it is absorbed from the lungs, for if an animal is drowned in water stained with a pigment the colouring matter can be traced into the pulmonary lymphatics. The disturbance of the circulation is as important as the disturbance of the respiration; when it begins to fail, the right heart is distended and the abdominal viscera are engorged with blood.

The methods which have been invented for artificial respiration may be divided into those which endeavour to draw air into the lungs, allowing the elasticity of the chest wall to produce expiration; secondly, those which try to drive out the air in the chest, trusting to elasticity for the re-introduction of fresh inspiratory air; and thirdly, those methods in which both inspiration and expiration are produced mechanically. At the present time only four methods are really in use. Marshall Hall's method is little employed at present, for in this country it has been almost entirely replaced by Silvester's method, and it may safely be said that the procedure advised by Silvester is the most widely employed at the present time. Howard's method is more used in the United States than in this country, but it is doubtful if it has any advantages over Silvester's. The latest procedure is Schäfer's and it is the method recommended by the committee of the Royal Society of Medicine appointed to considered the whole question of the best mode of resuscitating the apparently drowned. The committee was appointed at the request of the chief surgeon to the Metropolitan Police, the officers of which have for many years employed Silvester's method. Many experiments were performed and estimations were made as to the amount of exchange of air effected by the various methods. The report points out that the means used for the resuscitation of the apparently drowned must be adapted to the circumstances under which drowning usually occurs. They must be simple and capable of being carried out by a single person. The committee considered that the method devised by Professor Schäfer fulfils these conditions better than the others. Further, the prone position favours the escape of water and mucus through the mouth and nose; a larger amount of air can be made to pass in and out of the chest than by any other; the upward pressure on the diaphragm stimulates the heart and there is less risk to the abdominal organs. The Schäfer method was described fully by Dr. Keith in his third lecture and is not very widely known. The patient lies in the prone position with the face turned sideways, and the operator exerts firm pressure on the lower ribs and loins; this produces expiration and the removal of the pressure allows inspiration to occur. If this be done some 12 times a minute a very effective exchange of air occurs. The question naturally arises, Shall Schäfer's method replace those previously in use? Dr. Keith's answer is that when intelligently and skilfully performed Silvester's method is preferable to Schäfer's, but that Schäfer's method is simpler and therefore it is more easily carried out by the unskilled, though it is less effective. Most of Schäfer's experiments were performed on living beings, and as the elasticity and tone of the tissues in the living are not identical with those of the drowned the conclusions based on these experiments are not so trustworthy as if they had been derived from experiments on dead bodies. What is needed is a careful record of the methods employed in all cases, both successful and unsuccessful; if records such as these were available conclusions of definite value could be formed. In 1776, when JOHN HUNTER was asked by HAWES for suggestions as to the resuscitation of the drowned, as we have already mentioned, he laid stress on the need for the accurate record of the means used and the degree of success attending them, but the recommendation has not been followed to any large extent, for in most cases the accounts are of the most meagre description Dr. KEITH thinks that artificial respiration, however carefully performed, is not likely to be successful in more than one in 20 or 30 of the cases, but as it cannot be said beforehand which is the exceptional case artificial respiration should be performed with the utmost care in all. Appeals to the statistics at present available are vain. Successful cases are much more likely to be put on record than are those in which failure has occurred, but if we may judge by statistics every method has shown a large amount of success

---

[1] The Lancet, March 13th, 20th, and 27th, 1909.

We cannot look upon the results of artificial respiration at the present time as satisfactory. Many cases do, indeed, recover, but it is probable that many die who might have survived had suitable treatment been adopted. We do not deny the great progress that has been made in the resuscitation of the asphyxiated and we recognise the enormous amount of care which has been expended in these researches, but we feel that there is much more to be done. It is possible that the impulsion and extraction of air by means of a machine, provided that care is taken to see that it is not used to excess, may yet replace other methods when the mechanism is at hand, for a machine is tireless and thorough, and less room is left for want of knowledge. Dr. KEITH is to be congratulated on having chosen for his Hunterian lectures a subject of such interest and importance.

Annotations.

"Ne quid nimis."

A "TUBERCULOSIS EXHIBITION."

UNDER the auspices of the National Association for the Prevention of Consumption and other Forms of Tuberculosis a "Tuberculosis Exhibition" is to be opened in the East-end of London at the Art Gallery, High-street, Whitechapel, on June 2nd, 1909, by the President of the Local Government Board. It is intended that this exhibition shall visit subsequently other poor districts of London in turn and afterwards make an extended tour of the provincial cities and towns. The whole of the movement is, we understand, to be purely philanthropic and educational, and free from commercial enterprise and advertisement of any sort; further, there will be no charge for admission. An influential organising committee has been formed, the composition of which assures that the exhibition is in good hands. The chairman is Mr. George Harwood, M.P., and amongst the medical members are Professor G. Sims Woodhead, Dr. C. Theodore Williams, and Dr. Arthur Newsholme. Dr. H. Hammond Smith is the organising secretary. Whilst not entirely neglecting the scientific aspect of the subject, the exhibition will be chiefly of a popular and educational character, and will seek, by the help of diagrams, models, actual specimens, and other means, to bring home to the people the nature of tuberculosis, the extent of its ravages, and the possibility of its prevention and arrest, as well as the methods to be employed to effect these purposes. Roughly speaking, there will be seven sections, showing (1) the extent of tuberculosis by means of diagrams and statistical tables; (2) the causation of tuberculosis; (3) "where tuberculosis lurks," with photographs and models of overcrowded and unhealthy dwellings; (4) how tuberculosis is spread, indicating the modes of infection by expectoration and milk; (5) how tuberculosis may be prevented; (6) how tuberculosis is arrested; and (7) a special section devoted to tuberculosis in children. We wish the exhibition every success. We have frequently insisted that the most powerful factor in the fight against tuberculosis is education of patients and their friends. It is important, however, to take advantage of every opportunity to instruct the public generally as to the simple means which may be adopted to live as healthy a life as possible under varying circumstances. In the crowded parts of large cities hygienic surroundings are at their worst, and it is therefore suitable that this exhibition should be held in the East-end of London and in other large centres. By means of lectures and demonstrations doubtless much can be done to teach the inhabitants the precautions which should be taken to insure thorough ventilation of the living rooms and the means which should be adopted for the disposal and destruction of the sputum. At the same time care should be taken not to induce too great a scare in respect to the infectivity of tuberculosis, otherwise the unfortunate sufferers from the disease may be treated as the lepers of old and unjustifiable hardships inflicted on individuals. Medical ideas on this point have lately undergone revision.

WILL ARTIFICIAL SYNTHESIS EVER SUPPLY THE WORLD WITH FOOD?

THE advance in the price of bread last week, due to financial operations which no one can approve, revives in the minds of chemists the possibilities of synthesis when applied to food production. It must be admitted that triumphant as are the very numerous synthetic processes which have been devised by chemists, yet very few of these relate to the building up of food materials from their elements. It is true the sugars have been so fashioned, but how long, laborious, and expensive does the process prove! The most vital constituent of food, the nitrogenous portion, or protein, is a building yet uncompleted by man's effort, although excellent foundations have been laid by the masterly work of Fischer. The simple adjustment of materials in the plant which furnish the important starchy foods is understood to some extent, but no man has been able to imitate it successfully, albeit carbon, hydrogen, and oxygen surround him on every hand. Bricks there are everywhere, but he cannot group them. Yet another important factor in diet is fat, but no chemist has dreamed of a mill which will serve out fat on an intake of grass. The fact is, chemistry succeeds better in the work of destruction than in the work of construction, and analysis must necessarily precede synthesis, so that composition and constitution must first be learned. The forces which determine this composition and constitution are the crux of the whole question, and this is where man is beaten. His food so far can only be produced through the natural synthetic mediums, the plant and the animal; agriculture is a practicable matter, but the artificial synthetic factory is not. Will it ever be? There are not a few eminent scientific men who predict with confidence that the world's supply of food (it may be at a distant day) will be produced abundantly and constantly by humanly devised processes which will place questions of quantity on more certain bases than agriculture can promise to do. It is difficult not to be sceptical about such a contemplated consummation of man's ingenuity, and certainly much of the joy and romance of the world would be taken out of it if the rearing of plants and animals ceased to be a necessity of its existence. Still, the triumph which would imply that albumin, starch, sugar, and fat could be fashioned out of the mineral elements, carbon, hydrogen, nitrogen, oxygen, sulphur, and phosphorus is not beyond the bounds of imagination, only we must not wait for it to put an end to the "cornering" of the people's food.

DOUBLE HÆMOTHORAX IN MENINGOCOCCIC MENINGITIS.

DOUBLE hæmothorax is a very rare condition. At a meeting of the Société Médicale des Hôpitaux of Paris M. E. Apert reported a case, apparently unique, in which it occurred as a complication of meningococcic meningitis. A boy, aged three and a half years, was taken to hospital on Jan. 28th last in a state of collapse. The face was livid, the lips were pale, and the respirations were feeble and slow. He had been in good health until the previous day, when he awoke feverish; in the evening he vomited and cried. On admission pallor, coldness of the surface, feebleness of pulse and respiration, and general weakness were the dominant symptoms. The child lay prostrate and motionless on the bed and groaned. The abdomen was not retracted, there was no rigidity of the neck, and Kernig's sign was absent. The sounds of the heart could scarcely be heard and the respiratory murmur was very feeble. The child was covered with flea-bites, but there were also two purpuric spots of the size of a lentil on the lower limbs. The temperature was 99·3° F. In the evening the temperature rose to 101·1° and at 3 A.M. the child died. At the necropsy, on opening the thorax, the lungs had a greyish tint instead of the rosy colour which they show at this age. They appeared to be void of air and blood and were in a state of atelectasis, like the lung of a fœtus. On raising the lungs this condition was explained: each pleural cavity contained a gelatinous mass of clotted blood which occupied the whole of the costo-vertebral gutter and extended as high as the axillary line, pushing the lungs forward. In aspect and consistence the mass resembled quince jelly; in the upper part it was transparent and of a yellowish or slightly rosy tint, in the lower part it was thicker and brown. Evidently blood to the extent of more than a litre had been extravasated into each pleura. The peculiar appearance of the clot was due to slow coagulation, which allowed the red corpuscles to collect at the lower part. Slow coagulation is the rule in effusion of blood into the pleural cavity. But what was the cause of this effusion? The lungs and the pleuræ were quite sound. But the cellular tissue of the costo-vertebral gutter was œdematous and the intercostal and azygos veins were thrombosed and distended by black non-adherent clot. All the thoracic and abdominal organs were normal. On the convexity of the brain, in the fissures, and in the course of the vessels there were a dozen purulent subarachnoid tracts, the beginning of suppurative meningitis. There were no lesions at the base of the brain. Films of the pus showed in small numbers diplococci, mostly intracellular, which did not retain Gram's stain. The symptoms were thus due to the internal hæmorrhage. The child died before symptoms of meningitis had time to develop. The fact that the meningitis remained localised to some of the fissures on the convexity of the brain explained the absence of rigidity of the neck and Kernig's sign. The existence of hæmorrhagic forms of purulent meningitis is well recognised, but in the cases described the hæmorrhage has taken the form of purpura; sometimes hæmorrhage from mucous membranes has occurred, but never hæmothorax. Further, double hæmothorax is in itself a rarity. M. Apert has been able to find on record only two cases. Zahn of Geneva described one which resembles the case now reported in the fact that the vena azygos was thrombosed. M. Apert was unable to explain the connexion between the meningitis and the hæmothorax, and on reading this careful clinical account the difficulty will be recognised.

THE RETIREMENT OF DR. JOHN TATHAM.

WE learn that Dr. John Tatham, who has for many years been Superintendent of Statistics at the General Register Office, will shortly be retired under the age clause from his important post. Dr. Tatham has earned the gratitude of the medical profession generally, and in particular of those officially responsible for the public health of the country, by his admirable Supplementary Reports on the Mortality of England and Wales. His great statistical powers have ever been placed readily at the service of the medical profession where puzzling situations have arisen, and his exposition of medical statistics in the first volume of Allbutt's "System of Medicine" (second edition) is an introduction to a difficult subject which has been found of the highest value by many practitioners. We are informed that Dr. Thomas Henry Craig Stevenson, who has been assistant medical officer of the Education Branch of the Public Health Department of the London County Council, will succeed Dr. Tatham as Superintendent of Statistics. Dr. Stevenson is the joint author with Dr. A. Newsholme, the principal medical officer of the Local Government Board, of the "Graphic Method of Constructing a Life Table" and of other statistical papers. He was formerly assistant medical officer of health of Brighton, and he brings considerable experience to his new and important post.

THE LODGING ARRANGEMENTS FOR THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE central booking office of the Royal Hungarian State Railways has issued a circular letter, dated April 15th, to explain the arrangements made for lodging members of the forthcoming International Congress of Medicine to be held at Budapest between August 29th and Sept. 4th. The office states that it has been intrusted with the arrangements for accommodating visitors to the Congress for its whole duration, and intends to make these arrangements in advance by issuing "accommodation orders." Such accommodation orders will be for seven days in hotels and eight days in private dwelling-houses, on the understanding that the day of arrival at hotels is to be taken as August 28th, but at private dwelling-houses August 27th. Should the arrival at Budapest take place after these respective days or the departure from Budapest before Sept. 4th, no reimbursement will be made for the time the lodgings are unused. The following tariff of lodgings is given:—In hotels (arrival on August 28th and departure on Sept. 4th): rent for a stay of seven days, prices in kronen (which may be read as shillings): Series A: single bed, K. 70–140; double bed, K. 84–210; three beds, K. 105–245. Series B: single bed, K. 48–69; double bed, K. 64–83; three beds, K. 80–100. Series C: single bed, K. 48–69; double bed, K. 35–63; three beds, K. 42–79. In private dwelling-houses (arrival August 27th, and departure on Sept. 4th): rent for a stay of eight days, prices in kronen: Series D: single bed, K. 51–70; double bed, K. 76-100; three beds, K. 91-115. Series E: single bed, K. 31-50; double bed, K. 46-75; three beds, K. 61-90. Series F: single bed, K. 16-30; double bed, K. 30-45; three beds, K. 44-60. Such apartments may be engaged by the person who requires lodgings stating in which series and at what price he desires a room with one, two, or three beds and whether it is to be in an hotel or in a private house. He will be free to choose the price which he is prepared to pay according to the scale set out above, and this price must be sent to the central booking office in advance. In return for this remittance an "accommodation order" for an appropriate lodging will be sent to the applicant. The committee of the Congress has arranged that a commission of K. 8.50 per person shall be paid to the booking office in return for its trouble and expenses. This commission is to be sent at the same time as the rent and the receipt of it will be acknowledged separately. If a person thus taking a room should be prevented from attending the Congress and notify the fact before August 20th, the rent paid in advance will be refunded upon production of the accommodation order with a deduction of 10 kronen a head, but should such notice reach the central booking office after that date 20 kronen will be deducted for each person. We would add for our readers' benefit that members who desire to avail themselves of the proposals contained in this communication should consider them carefully and keep every document in connexion with their bargain, as failure to produce written evidence of similar contracts proved a fruitful source of trouble at the Madrid meeting of the International Medical Congress.

INFLAMMATION OF BURSÆ AND "RHEUMATISM."

IN spite of recent progress in diagnostic accuracy the term "rheumatism" is still used vaguely and is applied to many different conditions, often to any articular affection the nature of which is unknown. Bacteriology has done something to diminish the evil by separating from this miscellaneous group gonorrhœal and pneumococcic arthritis and acute rheumatism, but much still remains to be done. In the *Boston Medical and Surgical Journal* of April 1st, Dr. E. A. Codman has called attention to the fact that many obscure cases of pain about joints termed "rheumatism" are due to inflammation of bursæ or of the areolar tissue between the different planes of muscles. In the human body those tissues which move on one another and bear weight—namely, joints—have their points of friction defended by articular cartilage, but where there is much movement but no weight is borne a simple synovial membrane is interposed for the purpose of diminishing friction. Tissues which move on one another only to a [illegible] layer of areolar [illegible] and bursa. The cracking and snapping about joints which occurs in some persons is usually produced in bursæ. The very existence of most of the bursæ is often forgotten, and therefore an altered condition in them is not entertained in diagnosis, but no matter how small they are subject to inflammation. Normally their walls are very thin, but when inflamed they may become much thickened. Dr. Codman has recently called attention to the frequency and importance of inflammation of the subacromial bursa. Inflammation of bursæ may be due to injury, infection, toxic waste products in the circulation, and over-use. Dr. Codman thinks that the stiffness which occurs after unusual exercise is due to mild temporary inflammation of bursæ, tendon sheaths, and areolar tissue. The wonderful self-oiling mechanism of the body is thrown temporarily out of order. The bursæ become thickened with congestion and acute œdema, and their secretion becomes too viscid and fibrinous to allow easy motion. The areolar tissue being in a sense a compound bursa may also become inflamed. This Dr. Codman regards as the pathology of lumbago and "stiff neck." The function of the serous membranes—pleuræ, pericardium, and peritoneum—is the same as that of the bursæ, the diminution of the friction of parts which move on one another. Their inflammations may consequently be regarded as analogues of bursitis. This opens up an interesting field for comparisons when affections of bursæ have been more fully investigated; at present we have not much material for broad deductions.

THE EFFECTS OF WIRELESS TELEGRAPHY ON OPERATORS.

IT has been remarked that each step taken in the onward march of any applied science seems to bring into notice some fresh special pathological condition. Various previously unknown diseases dogged the steps of the earlier engineers, electricians, chemists, and balloonists. The dangers lurking in the Crookes tube—beneficent though it be when used under proper control—have been of late made tragically prominent. Amongst the numerous persons who are now learning to fly possibly some new pathological curiosity will before long come to be recognised. According to M. P. Bellile, a French naval surgeon on board the *Descartes*, which has been engaged in the campaign in Morocco, the members of the ship's company who were employed in wireless telegraph duty developed various affections in consequence of the action of the Herzian waves. Most commonly the telegraphists complained of their eyes, a slight conjunctivitis similar to that occurring amongst those who work with arc lamps being found. Although this of itself was not generally at all serious, yet in one case where the attacks recurred again and again, keratitis was produced which resulted in a leukoma of the right cornea and consequent impairment of vision. In order to protect the eyes from damage by the ultra-violet rays of the electric emanation, which have a very powerful action, it was recommended that yellow or orange glasses should be worn. Not only were the eyes of the operators affected, but two cases of eczema—one of the wrist and one of the eyelid, both very difficult to cure—were seen, probably due to the same cause. Lastly, one of the officials who had been employed for several years in wireless telegraphy suffered from painful palpitation of the heart which came on after working for any length of time at the instruments for sending messages. This man was quite free from any organic lesion of the heart. M. Bellile is disposed to think that a good many of the cases of "nervousness" and neurasthenia which seem now to be getting rather common among naval men may be due to the work which is being done in wireless telegraphy.

CONGENITAL NEPHRITIS.

THE kidneys of young children appear to be very susceptible to irritation from causes which have little or no influence in adult life. Thus, in addition to the ordinary causes of nephritis, such as passive congestion, ingested irritants, and the infections, such conditions as acute indigestion, inflammatory conditions of the alimentary tract, cold plunges, exposure to high degrees of heat, calcareous and hæmosiderin deposits in the tubules, interstitial hæmorrhages, and even icterus, may all be concerned in the production of nephritis in early life. Other causes are uric acid infarcts and parental syphilis, both of which may produce changes in the kidneys before birth. In the latter case the nephritis is usually of interstitial type, but parenchymatous changes occur in some cases. Dr. Howard T. Karsner contributes an interesting study of these conditions to the February number of the *Proceedings of the Pathological Society of*

Philadelphia and records a case of acute parenchymatous nephritis in a newly born infant. The infant was born of a healthy Irish woman and showed no sign of syphilis. The mother also presented no evidence of that disease, but no information was obtainable as to the father. Labour was normal and the infant showed no abnormality except cyanosis which persisted even after respiration had been established. Shortly after cutting the cord the child became more deeply cyanotic and death occurred about 45 minutes after birth, in spite of an attempt to inject strychnine directly into the heart. The mother made an uninterrupted recovery. Her urine was of normal character. At the necropsy on the infant both kidneys showed congestion of the cortex and injection of the pyramids, the lungs were found to be congested, the liver was in a state of cloudy swelling, and the foramen ovale in the heart was patulous. Histologically there were found interlobular fibrosis in the pancreas, mucoid degeneration of the gastric mucosa, and slight lymphoid infiltration of the small intestine. The kidneys showed changes characteristic of acute parenchymatous nephritis. No definite cause to account for the nephritis could be found. No indication of syphilis was apparent in the infant, and Dr. Karsner is therefore disposed to relegate his case to the type referred to by Holt as primary nephritis. After a careful search of the literature he finds but few references to similar cases, although Descroizilles, Cotton, Baginsky, and Henoch all mention the occurrence of nephritis at or shortly after birth, while Ashby and Wright affirm that infants may be born with acute nephritis and Ashby has recorded such a case. Dr. Karsner gives references to the literature of the subject and his paper forms an interesting addition to our knowledge of congenital nephritis.

FLOCK AS A POSSIBLE DISTRIBUTOR OF VERMIN.

OUR readers will remember that in THE LANCET of Jan. 23rd we gave an account of the process of manufacturing flock, both dirty and clean, as investigated by our Special Commissioner. The details of the former were disgusting in the extreme, but one department at least of the Government is alive to the dangers to public health which exist therefrom. An inquiry was set on foot by the Local Government Board in 1908 conducted by Dr. Reginald A. Farrar, whose report is to be published later. Part of the inquiry centred in the question of the limits of vitality of the vermin with which the materials used in manufacturing inferior flock bedding are sometimes infested, and this investigation was undertaken by Mr. Cecil Warburton, F.Z.S. The parasite selected was the body louse, *Pediculus vestimenti*, and after various experiments as to the best way of keeping the lice alive in incubators and feeding them on rats, which all failed, Mr. Warburton, with the heroism that marks the true scientific investigator, determined to make himself the *corpus vile*. He states: "Examples of Pediculus vestimenti were imprisoned, together with a small piece of cloth, in a glass tube about three inches by five inches, plugged with cotton-wool. The glass tube was inclosed in a metal case open at one end, to guard against possible accidents. The whole was kept close to the person, night and day, except when feeding was necessary, which was at least twice in the 24 hours. The tube was then opened and the small piece of cloth, with the lice adhering to it, allowed to fall upon the back of the hand." Here they fed. Lice were bred in this manner and their life-history was thus ascertained. The eggs were reared under the same conditions as the mother had been kept and finally the life-history could be detailed as follows. Incubation period, eight days to five weeks; period from larva to imago, 11 days; non-functional mature condition, four days; adult life, male, three weeks; female, four weeks. With regard to the possibility of flock acting as a transmitter of vermin experiments showed that lice would pass safely through the "devil," for stuffs known to be verminous were put through that ominously named machine, and in the sacks in which the flock was packed dead lice were found which had crept out of the flock after it was packed. They had therefore evidently not been killed by the tearing process. The conclusion of the whole matter was that lice, and *a fortiori* their eggs, may pass through the flock-making machine without being crushed. The lice themselves would most probably not be alive when the flock was converted into bedding, but as the eggs take a month or more to hatch it is quite possible that living eggs might be present in bedding. We await Dr. Farrar's report with interest, and it is earnestly to be hoped that the Local Government Board will take immediate and energetic action to stop the sale of filthy flock. An increase in price of about 2*s.* per bed would, as our Commissioner showed in his report referred to above, pay the manufacturer for purifying his flock before making it into bedding.

THE SPRINGTIME HOLIDAY.

THE sunshine of the late Easter week and the present weather indications point to the fact that those who are taking their annual holiday, or some portion of it, at this early period of the year have been well justified of their action. There is little doubt that the early autumn will remain the favourite season for the migration of townsmen to the seashore, the hills, or the moorlands, for the slackening of every kind of business in August and September has by now become so fixed a feature of the commercial and professional year that we can scarcely expect the date of the holidays to be moved forward by an earlier general exodus to the country. It is probable, too, that the majority of city dwellers prefer to leave their offices and streets at the time when we are accustomed to feel in England the hottest days and sultriest nights of the year. But the man who can arrange to leave his work in late April and early May either for his favourite golf-links or trout stream, or simply to wander on foot or cycle through the highways and flowering byways of the countryside he loves best, now that "Earth, unto her leaflet tips, tingles with the spring," provided only that he is blessed with rainless skies, will carry back to his work a sense of refreshment that the full-blown splendours of the countryside in early autumn can hardly afford him. And even if his mind be of such a cast that it neither regards the promise of the sweet of the year with special gladness nor feels any tinge of regret in the ripeness of harvest-time, if, in a word, all he asks of his holiday be a good table and a soft bed and fine days in the open air, he will still find that such things may be attained with more readiness and at a smaller cost in Maytime than in August, and he will, moreover, take his pleasure without encountering those congregations of his fellow-townsmen which everywhere invade the enjoyment of the autumn holiday. To those medical men whose work lies in towns the spring holiday may well bring a particular recreation of mind and body. The mere fact of getting away from the frets and ills of his fellow men, with whom in his professional life he comes into such constant and intimate contact, is of itself a refreshment, and, as we have said, this solitude is more easily attainable in the spring than in the autumn. We know that many medical men are only justified in leaving their practice at the time when many of their patients are away from home, but if the money can be sacrificed the return in health of the spring holiday—though only for few days—will be found very great. We acknowledge that most who are fathers of families, whether edical men or laymen, will feel themselves bound to e autumn holiday by the dates of their children's hool holidays, but, however unpopular be the suggestion, we venture to remark that in certain instances nd when funds permit a separate holiday for the readwinner may afford him a rest unattainable in the mpany of his family. In any case there are a large umber of childless practitioners to profit by our advocacy f the springtime holiday, which must, however, be read as onditional upon a reasonable attitude on the part of the eather, for a wet May will not only be as annoying as a et August but in all probability will be a good deal colder. ut we must close this recommendation of the spring holiday y admitting that the counsel to take it is a counsel of perection, for we know that medical men in full swing can ake only too often no holidays at all.

EDICAL MISSIONS AND THE SOCIETY FOR THE PROPAGATION OF THE GOSPEL.

THE 208th anniversary of this society will be held from pril 24th to 30th, and on April 28th at 8 P.M. a meetg will be held at the Church House in connexion with e Medical Missions Department. The speakers will inlude Sir Dyce Duckworth, Dr. F. H. Champneys, and Miss ane Walker, M.D. The connexion between the priest and e medical man is, of course, a very ancient one, and medical issions are one of the most valuable portions of mission ork, for the healing of the sick leads in very many cases those who are healed and their friends listening to e new message. The society appeals for fully qualified edical men and women, but, of course, the fulfilment of is idea will cost money. Not only does it involve the eep at least of the medical missionaries, but money is also eeded for hospitals and dispensary buildings and the supply f instruments, drugs, dressings, and the like. There is now movement both in medical and religious circles as to a loser union between the work of the physician and that of e priest, and the work of medical missionaries is one of the est ways of showing that these two offices may be combined one person without the functions of the one in any way fringing the responsibilities of the other.

A MODIFICATION OF THE CUTANEOUS TUBERCULIN REACTION.

THE cutaneous tuberculin reaction for the diagnosis of uberculosis was first introduced by von Pirquet and the echnique recommended by him was as follows. The skin, referably of the arm, where the test was to be made was horoughly cleansed and a drop of a 25 per cent. solution of Koch's old tuberculin was placed on the arm; the skin was hen scratched through the drop by means of a vaccinating ancet or Pirquet's raspatory. For purposes of control other cratches were made without the tuberculin having been pplied. Von Pirquet subsequently thought it better to use ifferent concentrations of the solution. After about one and half hours a very slight redness appeared at the spot of noculation and also at the spot of the control scratch. This as regarded as due to the slight traumatic irritation aused by the actual performance of the inoculation. This edness disappeared after an hour or two, and if a positive esult followed on the site of the inoculation of tuberulin, in about three hours a reddening of the skin ppeared, which increased until it reached a maximum; this sually took from 12 to 24 hours. In the *Répertoire de harmacie* for February a description is given of Lautier's odification of the above process. A pledget of cottonool of the size of a pea is moistened with three drops of a olution of tuberculin and applied to the unbroken skin on the outer surface of the arm. The application is covered with gutta-percha tissue and a pad of cotton-wool, kept in position with a bandage. It is important that the skin should be intact and cleansed with alcohol and ether just before the dressing is applied. Within 24 hours, if the reaction is positive, the patient will complain of irritation which increases during the ensuing 24 hours. The dressing is then removed, and, in the case of a positive reaction, redness and sometimes papules will be observed. The reaction may manifest itself within half an hour and varies in intensity as regards redness, swelling, dryness to the touch, and tenderness produced by pressure. The results of this method were controlled by the ophthalmic reaction.

THE NURSING AND MIDWIFERY CONFERENCE.

DURING last week a Nursing and Midwifery Conference and Exhibition was held in the Grafton Galleries, Bond-street, London, W. It was opened on April 14th under the chairmanship of Mrs. Stephen Glanville, and continued for four days, during which many matters important to the profession of nursing were dealt with in a series of debates. We may mention especially the remarks of Dr. T. O. Wood, who in reviewing the present position in the nursing world said that the chief want felt was a uniform system of training, examination, and certification; that a definite standard of proficiency might be reached which would entitle successful candidates to a qualification—not of this or that hospital—which might be a variable quantity—but of one great qualifying body. Nurses might broadly be divided into the following classes: (1) those trained at general hospitals in both medical and surgical nursing; (2) general hospital nurses who have in addition special hospital training, as in fever or children's hospitals; (3) obstetric nurses or midwives; and (4) male and female nurses trained in asylums to attend upon the insane. He referred to the several organisations that existed to register these classes—namely, the Royal British Nurses' Association, which was promoting legislation for the State registration of nurses, and the Medico-Psychological Association of Great Britain and Ireland, which had already one uniform standard of training, examination, and certification throughout the kingdom and the colonies. Dr. Wood also mentioned the Asylum Workers' Association, Queen Victoria's Jubilee Nurses, and the association known as the Midwives Institute. Dr. Wood said that he was glad to see that in the Bills before Parliament for the State registration of nurses the medical profession was well represented upon the proposed council. If State registration became an accomplished fact the scale of fees would have to be arranged upon a reasonable basis, as otherwise many nurses would be debarred from registering and the movement would be a failure. On the same day a discussion was held upon the period of time requisite to train midwives in aseptic principles, when it was generally agreed that the three months enforced by the Central Midwives Board was inadequate for the purpose and that a year's training was desirable. On the last day of the Congress Dr. David Walsh dealt with the vexed question of hospital accommodation for the middle classes.

CONDEMNED FOOD.

THE annual report of the Manchester Port Sanitary Authority shows that instead of becoming less there is a large increase in the amount of condemned food-stuffs. It may be remembered that not very long since Liverpool traders protested against what they seemed to consider the undue severity of the tests used by the Manchester authority. The gross total of condemned food was 881 tons, a large increase on the 216½ tons condemned during the ten months in the previous year. Of grain, 694 tons have been seized and dealt with, the greater part having been released on the medical officer having been satisfied that the particular parcels would not be used for human food. It may be desirable now and then to follow some of these parcels in the changes they undergo in the process of manufacture, so as to make sure that humanity is not fed with them. As is always the case, it is the small percentage of wrong-doers who create the necessity for what might be termed the "policing" of the whole system of this class of trade. There was rather a large importation of pigs' tongues, packed in barrels and preserved in what is known to the experts as "patent pickle." On analysis two points came out in the report, viz.: "That the sample containing the larger proportion of preservative showed the greatest amount of decomposition as gauged by the amount of carbonate and free ammonia; and that the tongue contained a larger percentage of boracic acid and a less percentage of sodium chloride than the liquor." The report deals also with the need for a proper definition of the terms "diseased, unsound, unwholesome, or unfit for the food of man." There seems to be a very prevalent idea among importers that articles should not be condemned unless it can be distinctly proved that they are unfit for the food of man, i.e., unless they may be supposed to exercise a distinct injurious influence on the human organism. This raises a curious question. Will a set of "vile bodies" be set apart for experiment? Probably some authority will have to go to the High Court, if not further, for a proper legal definition to be framed.

THE SECOND INTERNATIONAL MEDICAL CONGRESS FOR INDUSTRIAL ACCIDENTS.

THE Permanent Committee of the International Medical Congress for Industrial Accidents after the first Congress, which was held in Liège, selected Rome for the site of the second Congress, as our Italian correspondent announced in a recent letter. The Italian organising committee appointed an executive committee to settle upon details and the date of the Congress was fixed for May 23rd to 27th. The matters to be discussed at the Congress are founded upon the idea that medical science ought to do its best for the just application of social laws, for the protection of workers, and for the due development of industries and of social well-being. The committee has therefore drawn up the following programme of subjects for discussion: 1. The organisation of a medical and surgical service for the treatment of industrial accidents and for the watching of their remote consequences. 2. Forensic medicine in relation to industrial accidents and the principles by which experts should be guided. 3. Diagnosis and prognosis of neuroses brought about by industrial accidents. 4. Estimation of capability for work before and after accident. 5. The influence of the various ways of compensation upon the evolution of post-traumatic nervous affections. 6. Statistical observations from the medical point of view as regards the application of the law bearing on industrial accidents. 7. Capacity for useful work of organs injured in industrial accidents. Members attending the Congress can read papers upon matters connected with industrial accidents, other than those suggested in the above programme if they like. The subscription to the Congress is 20 francs for members, for ladies and associate members 10 francs. These sums should be sent to the treasurer, Professor A. Asarelli, 38, Via Borgognona, Rome. The President is Professor Salvatore Ottolenghi, and the general secretary is Dr. Tito Ferretti. Though it is unlikely that many British medical men will be able to afford either the time or the money to attend the Congress, yet it is to be hoped that a goodly number will be able to send 20 francs to the treasurer for the sake of the literature which will follow hereafter. Diseases and accidents due to employment are day by day taking a more important place in medicine and surgery, and the reports of this Congress cannot fail to be of interest and of value.

Dr. Arthur Eastwood, bacteriologist to the Royal Commission on Tuberculosis, has published a report dealing with the methods adopted in various American States for the control of tuberculosis amongst herds of cattle, for the protection of human beings from bovine tuberculosis, and for the supply of clean milk. This report, which we shall consider in a future issue, was the outcome of an investigation made by Dr. Eastwood at the conclusion of the International Congress on Tuberculosis held last year at Washington by the desire of the President of the Local Government Board, under whose authority the report is published.

A TELEGRAM from the Governor of Hong-Kong to the Secretary of State for the Colonies states that 7 cases of plague were reported during the week ending April 17th, and that the number of deaths was 6. A telegram from the Officer Administering the Government of Mauritius to the Secretary of State for the Colonies reported the occurrence of 2 fatal cases of plague on April 17th.

WE regret to announce the death of Mr. Simeon Snell, F.R.C.S. Edin., which occurred at Sheffield on April 17th. Mr. Snell was elected President of the British Medical Association at its annual meeting last year and was ophthalmic surgeon to the Sheffield Royal Infirmary.

Dr. J. Lucas-Championnière, president of the International Surgical Congress, has consented to deliver the annual address to the Cardiff Medical Society on Friday, June 4th. The subject of his address will be the Treatment of Fractures.

THE ROYAL SANITARY INSTITUTE.—The *President*, his Grace the Duke of Northumberland, will preside at the annual dinner of the institute, to be held on May 11th at the Langham Hotel. A meeting of the institute will be held in the medical theatre of Birmingham University on May 8th, at 11, A.M., under the chairmanship of Colonel J. Lane Notter, R.A.M.C., when Mr. J. Malcolm, F.R.C.V.S., veterinary superintendent to Birmingham corporation, will open a discussion on Tuberculosis and the Milk-supply.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on April 14th, Dr. G. F. Blandford, the President, being in the chair. 11 directors were present. Since the last court three members of the court had died—Mr. T. Laurence Read (vice-president), and Mr. G. Eastes and Mr. Charles E. Baker (directors). A vote of condolence was passed to the families of these gentlemen. Application for membership had been received from two medical men and they were duly elected members of the society. One of the annuitants, an orphan, had died. Her mother up to the time of her death had also been in receipt of grants. The father had paid in subscriptions £14 14s. and his widow and orphan had received from the funds of the society £960. Five letters asking for relief had been received from widows of medical men, but this had to be refused as their husbands were not members of the society. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20 mile radius of Charing Cross. The subscription is 2 guineas per annum, and relief is only granted to the widows and orphans of deceased members. Full particulars may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London, W. The invested funds of the society now amount to over £100,000. [illegible] May 20th, was fixed for the annual [illegible] notice of which will be posted to the members on May 1st.

SOME HITHERTO UNKNOWN CENTRES OF ENDEMIC PLAGUE IN THE KIRGHIZ STEPPES.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

RATHER more than a year ago the Russian [illegible] Commission issued a volume of nearly 500 [illegible] with the subject of plague outbreaks in the country about the mouths of the Volga, in the Astrakhan government, in the *Kirghiz Steppes*, and adjoining regions. The volume[1] has only now reached my hands; it throws valuable light on the records of a series of epidemics, many of which have hitherto escaped notice in other countries and which are of the highest epidemiological interest and importance. A brief summary of the contents of this volume will be of use to many readers of THE LANCET.

The work is divided into three parts: the first is entitled "Plague in the Astrakhan Border, its Epidemiology, and a General Review of the Measures Taken;" the second, "Individual Inspection of the Population of the Inner Bukéef Horde and Adjoining Regions;" and the third, "Trade Routes in the Inner Bukéef Horde and Adjoining Regions." Each section has been written by *medical officers*, *and the investigations* were entirely conducted in connexion with the plague outbreaks and with a view to throwing light on their character and origin and on the best means of controlling or exterminating the disease.

In the first section an account is given, so far as it is known, of the records of plague in these regions from the earliest times down to the famous epidemic in Astrakhan in 1877 and that in Vetlianka and other villages on the Volga in 1878–79. The authors believe that before the nineteenth century the historical plague outbreaks in Russia always had their origin in the west and that the Astrakhan border played no part in their etiology or spread. On the other hand, in the two principal epidemics of the nineteenth century, those of 1807–08 and 1877–79, the disease undoubtedly came to Russia through those regions. The Astrakhan and Vetlianka epidemics they believe to have been caused by an imported infection from the endemic centres of plague in Mesopotamia. Those outbreaks were thought to have been the last in Europe before the date of the recent revival of the disease in China and India and, in more or less pandemic form, through a great part of the world. But, as the following list shows, there was an epidemic on the northern shores of the Caspian Sea some time in the "eighties" of last century, and the first of two epidemics in Aksai occurred as early as 1896, or at a time when the pandemic of plague had not, as far as was hitherto known, spread beyond India and China.

The following is the complete list of plague epidemics (known or suspected) in the Astrakhan border since 1877:—

[illegible]

Irsaly-Aral

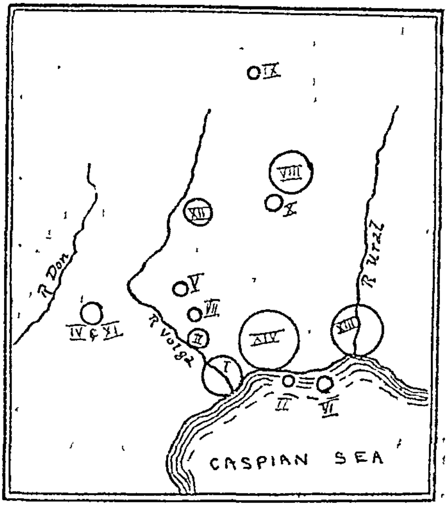
VII. 1900–01.* In Vladimirovka (Tsaref *uyezd* of Astrakhan government)

VIII. 1900–01.* In the Talof region of the Inner Horde (in four settlements)

[illegible]

(Caspian Sea)

An asterisk in this list indicates that bacteriological proof that the disease was plague was available. The scene of each outbreak is shown by means of a circle with the corresponding Roman figure in the accompanying map (modified from a large and detailed map in the volume under notice). There were thus 14 outbreaks in 28 years, including some that passed at the time almost or quite without record and are only presumably examples of plague outbreaks; the presumptive evidence is, however, in most instances very strong. The authors of the report believe that the infection of the 1877–79 outbreaks never died out; that for some 20 years it produced occasional epidemics, which caused little remark, though in some instances they led to a very high mortality (as near Djambai in the "eighties"); and that since 1899 [illegible] endemic, causing yearly epidemics [illegible] egion bounded on the east by the [illegible] y the Volga and the country adjoining the angle where the Volga approaches the Don, on the south by the Caspian Sea, and on the north by the Novouzensk district of the Samara government. The reports are accompanied by a series of valuable maps and diagrams and charts, fully illustrating the history and geography of these various outbreaks, and greatly facilitating the comprehension of this little known chapter in epidemiology.



[illegible]

The 1877–79 outbreaks have been too often described to need any further reference here. There follows a period of 17 years of doubt and uncertainty. Some time in the "eighties" of last century a deadly epidemic occurred on an island inhabited by Kirghiz, situated at the north end of the Caspian Sea and not far from the village of Djambai on the mainland. No skilled observer saw any of the cases. The local authorities sent a steamer to the island with a commission instructed to investigate the outbreak; but, "it is said," none of the commissioners dared to land for fear of the infection; they contented themselves (again "it is said," in the words of the report) with throwing overboard two bottles of brandy for the wretched islanders. Every inhabitant of the island is said to have died. It is uncertain whether the disease was actually plague, as the most prominent symptoms were said to have pointed to some cerebral affection; but the authors of the report are none the less inclined to believe that it was an outbreak of plague.

[illegible] of plague in these regions declared that he saw a similar fatal disease in the place and at the time just named, that the symptoms were identical, and that about 40 deaths occurred on the earlier occasion.

In 1896 occurred yet another unrecorded epidemic; this was in the village of Aksai, in the Tcherno-Yar district of the Astrakhan government. The village is situated on the

---

[1] Sbornik Rabot po Tchumye. Edited by Dr. V. I. Isaief, Honorary Physician to H M. the Tsar.

Aksai, a stream which flows into the Don. In September, 1896, a fatal disorder broke out among the 2000 inhabitants, and in the course of three months caused the death of some 60 persons. When six years later the epidemic of plague (proved bacteriologically), which is described below, occurred here it was recognised that the mortality in 1896 must have been due to the same disease. Several whole families were carried off by the infection. The district medical officer, who lived at Tcherno-Yar, 113 versts from Aksai (this detail throws a lurid light on the situation), described the disease as typhoid fever with enlargement of glands, particularly in the groin, and occasionally with petechial rashes, and added that it was very infectious and fatal.

In 1899 came the Kolobovka epidemic. This village is situated in the Tsaref *uyezd* (district) of the Astrakhan government. The disease—a very infectious form of pneumonia—appeared there on July 16th, and between that date and August 12th there were 24 cases with 23 deaths; only one person, a woman, aged 51 years, recovered. By this time plague, both bubonic and pneumonic, was becoming once more a known disease; the bacillus had been identified and diagnosis was relatively easy. Material from these cases was examined by experts and was found to contain the Yersin bacillus. This outbreak was described by me at the time (from Russian sources) in the columns of THE LANCET.[2]

In October of the same year plague broke out on the islands of Irsaly-Aral, Kishkiné-Aral, and Kiné-Aral, at the northern end of the Caspian Sea. The outbreaks on the two last-named islands were also described by me at the time in the pages of THE LANCET,[3] but not that on Irsaly-Aral, which was not mentioned in the Russian reports published at that period. In Irsaly-Aral, out of a population of 52 (Kirghiz, living in *aouls*) 25 were attacked by the disease and 22 died, only 30 thus remaining alive. In the other two islands, out of a total population of 64, 39 were attacked and all died, leaving only 25 living. The bodies of the dead remained unburied, the survivors fearing to touch them. No living cases were seen by medical men in Kishkiné-Aral and Kiné-Aral, and only moribund cases in Irsaly-Aral. No bacteriological examination was made, but clinically and from the appearance of the bodies after death the disease was believed to have been plague, apparently of the pneumonic variety. The outbreak was apparently self-limited.

In December, 1900, plague was recognised in the Vladimirovka *sloboda* (= large village), again in the Tsaref *uyezd* of the Astrakhan government, lying on the left bank of the Volga, 150 versts south of Tsarytsin. The outbreak probably began in September. 18 cases of the disease were registered and of these 16 died. The disease was bubonic in character; the cases were seen on this occasion by medical men, and detailed clinical histories, with temperature charts, are published with the reports. Bacteriological examinations were also made and established beyond doubt that the disease was in fact the plague.

On Dec. 23rd (Old Style), 1900, the existence of a fatal disease was reported from the *urotchishché* (= collection of *zemlianki*, or half-underground earth-huts) of Tekebai-Tubek. This is situated in the Talof region of the Inner Kirghiz Horde, 40 versts from the railway station of Alexandrof-Gai and 18 from the town of Talovka. The disease apparently began in another *urotchishché*, that of Atchikbai, 25 versts further south; then spread to Tekebai-Tubek; later it appeared in a third, that of Mereké, eight versts from the second; and still later was carried by refugees to a fourth, that of Karakuga, on the borders of the Uralsk province. In the first three places, in the course of a month and a half, the disease appeared in 28 different earth-huts (23 in Tekebai-Tubek, four in Mereké, and one in Atchikbai). There were 154 cases in all and 140 deaths (124 in Tekebai-Tubek, 13 in Mereké, and three in Atchikbai). The total population of the infected huts was 174, so that 90 per cent. of these fell ill and 80 per cent. died. In 15 huts, containing 74 persons, every person died. The disease was apparently pneumonic plague; neither buboes nor petechiæ were seen in a single case. Necropsies (made in 14 cases) and bacteriological examinations showed that the disease was pneumonic plague, with, in some instances, a mixed infection with the plague bacillus and the pneumococcus. In Karakuga there were 14 cases and 13 deaths. But here energetic measures were taken to put an end to the epidemic, including the isolation of the sick and the inoculation with Haffkine's prophylactic of 170 persons, and the outbreak declined from the moment these measures were put in force.

In March, 1901, an outbreak of plague was discovered in the village of Alexandria, in the Novoüzensk district of the Samara government, immediately adjoining the above-named Talof district of the Inner Horde. The village lies on the same stream (the "Little Uzen") as Tekebai-Tubek, just named above. The disease appeared there in the later months of 1900. No case was seen by a medical man. Out of a population of 424 over 60 died. In the early months of 1901 a few more deaths occurred; a bacteriological examination was then made in two instances, but the plague bacillus was not found. Nevertheless, the authors of the report believe the 1900 outbreak to have been one of plague, most of the cases being of the pneumonic variety, and that there was probably a mixed infection with the plague bacillus and the pneumococcus. Some cases of anthrax (proved bacteriologically) occurred about the same time and gave rise to the theory that the outbreak was not one of plague but of anthrax. On the other hand, it is pointed out that the latter disease is of frequent occurrence in these regions, that plague and anthrax have on other occasions been seen to coexist and instances are quoted (in detail) of persons suffering from the two diseases at the same time. The existence of anthrax in the village does not then exclude the possible presence of plague, and the fatal epidemic in the village of Alexandria is thought to have been of the same nature as that in Tekebai-Tubek and the adjoining places.

In 1902 two plague outbreaks occurred in these regions: the first in the *urotchishché* of Ush-Kuduk, in the Talof region of the Horde, where six cases and five deaths were recorded, and the second in the village of Aksai, already mentioned as the scene of an unrecorded epidemic in 1896; here 33 cases and 20 deaths were registered.

In 1903 plague appeared in the village of Buikof, in the Tsaref *uyezd* of the Astrakhan government, and in three adjoining *khutors* (= large farms), bearing the names of Bulukhta, Muguta, and Zubof; 14 cases and 12 deaths occurred in all. The diagnosis of plague (bubonic) was confirmed by bacteriological inquiry; here again anthrax (also proved bacteriologically) was prevalent at the same time

In 1904 a much more serious outbreak occurred in the Gurief *uyezd* of the Uralsk province. The Kirghiz inhabitants of three villages—Yamankhalinsk, Saraitchikof, and Sorotchinsk—situated 35 versts along the postal track from Gurief to Uralsk and on either side of the Ural river were affected; between Nov. 1st, 1904, and Jan. 4th, 1905, no less than 415 deaths occurred.

An even more deadly epidemic broke out in 1905. In August of that year plague appeared in the *Primorskia* ("Maritime") districts of the Astrakhan government, in the Narynsk region of the Horde, and on the island of Fedr; all these districts are at the north end of the Caspian Sea The existence of the outbreak here only became known two months after it had begun; then when a medical mission arrived on the spot over 500 dead bodies were found in 42 different *urotchishchés*. No exact figures were available as to the number of cases or deaths, but approximately it was reckoned that 565 persons fell ill and 527 died. The proportion of cases to the whole population was no less than 65 per cent.

This completes the list of outbreaks dealt with in the volume under notice. It will be seen that it brings the records down only to the year 1905. Other epidemics have undoubtedly occurred since; as late, indeed, as last summer it was reported that nine cases with four deaths from plague had occurred among the Kirghiz inhabitants of the steppes of the Astrakhan government.[4] No further details were available at the time, and it may be hoped that the Russian Plague Commission will continue to publish—and at not too long intervals—reports on the further history of the disease in these regions as full and detailed as those in the present volume.

It is clear from the foregoing that the stretch of country about the mouths of the Volga and Ural rivers must be regarded as, for the present, a true endemic area of plague, comparable to those that formerly existed in Mesopotamia, in portions of Persia, in Assyr, and elsewhere. It is also clear that the practical difficulties in the way of stamping out the disease in this area are very great. Fortunately, however, just as in the case of the other historical areas of endemic plague just mentioned, the disease does not show any tendency to spread from the infected regions to others and thus to cause a widespread epidemic. The Kirghiz Steppes hold little direct communication with the rest of the world and thus the danger is limited. But for the inhabitants of those isolated regions the danger is great, one might say terrible, as is shown by the above-quoted records of whole households, whole villages, whole islands losing their entire population in the course of a few weeks or months from the deadly disease with no outside help and no hope of escape.

---

[2] THE LANCET, Sept. 16th, 1899, p. 810.

[3] THE LANCET, Feb. 3rd, 1900, p. 351.

[4] THE LANCET, Oct. 3rd, 1908, p. 1040.

There is no doubt that the Russian authorities realise the situation, and the excellent work recorded in the second and third sections of the volume under notice should prove of great value in laying the foundations for practical remedial measures. In the second section a full account is given of the ethnolc [illegible] he infected regions, including an [illegible] the various types met with, their [illegible] and mode of life; of the climatology, flora and fauna of the country; of the vital statistics, so far as known, of the inhabitants; of the principal reigning diseases; of the existing provision for medical aid; and, finally, of the results of an individual inspection of the entire population not only of the Inner Bukéef Horde of Kirghiz but also of the Uralsk province and of Transcaspia. Finally, the third section deals with the trade routes in these regions and the principal lines of communication between them and other territories in Europe and Asia. It is unnecessary to give here even a summary of these chapters in which the matter is discussed from the point of view of history.

A vast mass of material of a highly interesting and useful character (and that not solely from the medical point of view) has been brought together in these reports, and it is a matter for regret that they appear in a language but little known outside Russia. Before closing this brief summary it should be added that in none of the plague epidemics above described was there evidence of the disease being spread by rats or other rodents. At the time of the Kolobovka outbreak 4128 different animals (including rats, mice, bats, marmots, snakes, and many domestic animals) were examined, and in none of them was the plague micro-organism detected. In the Vladimirovka outbreak and in those at Tekebai-Tubek and adjoining places inquiry was specially made as to the occurrence of mortality among rats, and in both with negative results. The authors of the report consequently come to the conclusion that rats and other rodents have not played any part in the spread of plague in these regions, though they are careful to add that the evidence is only presumptive and incomplete, and that caution is necessary in any case in coming to an absolutely negative conclusion.

Constantinople, April 3rd.

SANITATION IN INDIA.

II.[1]

Bengal.

THE fortieth annual report of the Sanitary Commissioner for Bengal for the year 1907 has been furnished by Lieutenant-Colonel F. C. Clarkson, I.M.S., the Sanitary Commissioner for Bengal. In it we find recorded remarks on the meteorology, vital statistics, chief diseases, vaccination in the Province, sanitary work, and the work of the Sanitary Board, with certain appendices. With respect to the meteorology, we learn that there was practically no rainfall in January in Lower Bengal, but that there were very heavy rainfalls during the next three months, that in Orissa being exceptionally heavy. In June although the south-west monsoon was actively established about the normal date yet it was restricted to a comparatively small area. The October rainfall was unfortunately defective in all districts, thus exercising a prejudicial influence on the winter rice crop.

With regard to the vital statistics, the number of births and deaths registered during 1907 amounted to 1,905,425 and 1,906,192, as compared with 1,885,725 and 1,823,243 respectively for 1906, the corresponding ratios being 37·70 and 37·72, and 37·32 and 36·08 per 1000 of population. The deaths were thus 82,949 and the births 19,700 in excess of those of 1906. The high price of food grains and the general unhealthiness of the year 1906 appear to have devitalised a large proportion of the people and checked the normal growth of the population. Compared with the other provinces, Bengal and Assam now come fourth and fifth. The experiment started in 1906 in the district of Burdwan for testing the registration of vital statistics in rural areas was continued throughout 1907. The usual inequality of births at different times of the year was very well marked, the registration at Murshidabad, for example, during June to September being very distinctly below the four months October to January, the only explanation which is apparent being that during the months of hard work in the fields there is a relative sterility which is compensated for by the opposite condition in the months after the harvest is gathered. With the single exception of fever the mortality from all the other causes was as usual higher in towns than in rural districts. Notwithstanding its filtered water-supply the cholera death-rate in Calcutta was only slightly smaller, probably due to the use of unfiltered Hooghly water for drinking and to flies settling on the food.

Coming now to the history of the chief diseases, we see that the mortality from cholera was unusually heavy, heavier even than that for 1906. In fact, 1907 was the blackest year on record except 1900, when the loss of life from this disease was the heaviest ever registered. There were 205,702 deaths as contrasted with 138,999, the average of the five years 1902-06, the corresponding ratios being 4·07 and 2·75 per 1000. This heavy mortality was probably due to the increasing pollution of the water-supply and the use of unwholesome things by the poorer classes in consequence of the abnormal rise in the price of foodstuffs. No district enjoyed complete immunity from it. Other causes noted for this large mortality were the use by the people of the beddings of cholera patients without proper cleansing, the throwing away of dead bodies instead of burying or burning them, thus contaminating the nearest water-supply, and eating unripe fruit. The wells were disinfected with permanganate of potassium with good result in a part of Burdwan and Midnapore only. Whenever this was properly carried out it was found that cholera was stopped in the locality. The people seem to be gradually beginning to appreciate the value of this measure.

Small-pox in 1907 maintained the upward tendency of the mortality noticed in 1906. The plague mortality went up, there having been 83,602 deaths, as against 59,619 of the preceding year; more females than males died. Captain Swanzy, R.A.M.C., who was in medical charge of the cases at Jalapahar, with his hospital assistant, compounder, and bhisti, fell victims to the disease. We are glad to note that anti-plague inoculation is gradually gaining in popularity, there having been 2766 inoculations, against 1777 in 1906 and 1544 in 1905. Among the inoculated one case of plague is reported to have occurred at Bhagalpur and one death at Champaran. The latter had almost certainly become infected before the operation. In Calcutta 3123 were inoculated, as against 101 in the previous year. No case of plague was known to have occurred amongst this number. Evacuation is the measure chiefly relied on, chemical disinfection having been practically given up. As a measure against fleas crude oil emulsion was used as a disinfectant. Much has been done also in educating the populace by means of pamphlets and instruction in plague prevention. Rat extermination was also carried out in many places of the province; 541,313 rats were killed in the Jagadispur circle of the Shahabad district. Fever prevailed with greater severity in 1907, 1,171,540 persons succumbing to it, as against 1,132,579 in 1906. Dysentery and diarrhœa showed also an increased number of deaths, giving a ratio of 1·02, as against 0·96 in 1906, the excess in mortality being probably due to the greater prevalence of cholera in 1907, the same causes contributing to both these classes of disease.

With reference to the sanitary work undertaken there was a very satisfactory increase in the expenditure under the important heads of sanitation—viz., conservancy, drainage, [illegible] -supply. Much attention has, we are g[illegible] [illegible] paid to the latter with respect to [illegible] also been directed to the disposal [illegible] re has been paid to the observance and medical precautions at all important fairs and festivals during 1907 with respect to the public and semi-public wells. Lieutenant-Colonel Clarkson is to be congratulated on the excellence of his report.

Central Provinces and Berar.

Lieutenant-Colonel A. M. Crofts, I.M.S., contributes the annual sanitary report for the Central Provinces and Berar for the year 1907. In these districts the climatic conditions were decidedly abnormal, there having been an unusual amount of rain in the cold and hot weather, a delayed and weak monsoon during June and part of July, very heavy rain during the rest of July and August, and drought during the last four months of the year. These conditions were in marked contrast to those of 1906, which was a decidedly unhealthy year, but they were not much conducive to better health except as regards the diminution of autumnal fever due to the early withdrawal of the rains. The mortality was 41·70 per 1000, and no year in which the mortality is as much as 40 per 1000 can be described as healthy. The birth-rate—52·46 per 1000—was again the highest in India, it only having been exceeded in 1905 and 1904 out of the last 25 years. The death-rate was 38·96 per 1000, but it is in reality not nearly so high as the official record shows when we consider the allowance that must be made for the influx of people attracted by the commercial development of the province and the return of emigrants who were temporarily absent at the census. The terrible waste of infant life, as a result of bad feeding, exposure and ignorant treatment, early marriage, and generally insanitary surroundings, must be looked for until education, and especially female education, is more widely diffused.

With respect to the chief diseases, the province suffered from two distinct epidemics of cholera, the first, a mild one, from January to June, being traced to the return of pilgrims from the Allahabad, Benares, and Puri fairs. The sources of infection in both epidemics probably were the fairs, the drying up of wells and tanks, and the consequent necessity of drawing water from jhirias sunk in the polluted beds of streams and nullahs, the spread of the disease being favoured by the gathering together of large parties in connexion with the marriage season. Small-pox showed, generally speaking, a decreased death-rate, but in Mandla this was not the case, which is put down to bad vaccination in the past few years. The exact prevalence of malaria was difficult to estimate, as there was reason to suspect that plague and many other diseases attended with febrile symptoms were registered under this heading; the incidence of these diseases as judged by dispensary statistics was lower than usual. The anti-malarial operations undertaken in the headquarters town of Betul were continued; it was not found possible to exterminate the mosquitoes, but their numbers are greatly reduced, as the natives are now finding out the danger of leaving stagnant water near their houses. Packets of quinine have been sold during 1907 in a more extended manner. With regard to diarrhœa and dysentery, there was a high mortality in Berar due to some extent to the consumption by the poorer classes of old damp and mildewed juari from earthen pits in which the grain is sometimes stored for years. The mortality from respiratory diseases was 1·24 per 1000 in excess of the preceding year, being at the rate of 2·64 per 1000; this may be partly due to the people living in temporary huts during the prevalence of plague, as they do not afford protection from the weather, and partly to better registration.

Coming now to plague, we find 37,774 deaths reported, more than half of which occurred in the Berar division. The special measures adopted for its prevention and spread continue to be inoculation, evacuation of infected areas, and destruction of rats. The prejudice against and suspicion of official methods of treatment have gradually become less widespread. Preventive measures are much more willingly undertaken in those places that have suffered severely in the past, in contrast to those districts that have not been so greatly attacked. Inoculation has not been so popular as was expected, but still a large number of operations were carried out chiefly through the tact and ability of Captain Morrison, I.M.S. There were 14,440 cases inoculated; the carrying out of this precaution is shown to have been much aided by the example and assistance afforded by the leading men of the district, Baboo Bakthanar Singh being especially praised in this direction. Such assistance, it is to be hoped, will be the rule in the future, as it is impossible for the overburdened civil surgeon in charge of large and populous civil districts to afford the time necessary to induce the people concerned to protect themselves by this method. It was found that the immunity period gained by inoculation was about two years. A wise endeavour is being made to check as far as possible the degree of immunity conferred, so as to place before the eyes of the people object-lessons in the persons of the inoculated who have escaped, whilst the uninoculated have succumbed. Lieutenant-Colonel Crofts wisely insists that inoculation, evacuation, and sanitation hold the chief places in prevention, and that while rat destruction is a valuable aid to these measures, it must not be considered superior to them. Lieutenant-Colonel Buchanan, I.M.S., is convinced that the most effective method, however, in this respect is to keep cats, and he states that where the percentage of cats in houses is large, there an epidemic will not occur.

With respect to snake-bites, 39 cases were brought to the various dispensaries, 24 of which were treated with Calmette's antivenene, of which 18 recovered and six died. Permanganate of potassium failed in cases which were subsequently treated with success with antivenene; it is successful where the echis is concerned, although apparently it is not so with the Bungarus cæruleus. Lastly, it may be noted that 209 cases of cancer were treated in the dispensaries. The report concludes with an account of the various sanitary works undertaken by the Public Works Department.

North-West Frontier Province.

Lieutenant-Colonel G. W. P. Dennys, I.M.S., in his report on the sanitary administration of the North-West Frontier Province for 1907, deals in like manner to the reports which we have been considering with all the sanitary details of the district under his charge. In this province there were 62,[illegible] births registered in 1907, against 76,834 of the previous year, the latter being the highest on record since the formation of the province, the ratios per 1000 being 32·5 against 38·6 for the respective years. The decrease is attributed largely, if not entirely, to the severe malarial fevers, followed by the usual sequelæ, that occurred during the first three months of 1907. This not only reduced the proportion of child-bearing women but also impaired the fecundity of the remaining population. With the exception of Madras, the birth-rate of this province was the lowest in India. There was a marked preponderance of male over female births. With respect to the rate of mortality there was a decrease of 172 on that of 1906—namely, 67,017 in contrast with 67,1[illegible], the death-rate per 1000 being 35·1, against 33·7 in the previous year; the mean death-rate for the five previous years was 29·6. The first two months of the year showed a very heavy mortality, due to the severe malarial epidemic occurring in the autumn of 1906. The mortality also was heavy in November and December of 1907 owing to the unusually early and severe onset of cold weather, when the people were still suffering from the effects of autumnal fevers. As usual, the latter head the causes of death, the rate being 27·4 per 1000, against 26·1 of the previous year.

Plague, from which the province had been so long immune, at last crossed the Indus and became for the first time epidemic. The outbreak in Peshawar was traced, it is believed, to the importation of a rat dead from plague in a consignment of grain. A few days after this the shopkeeper noticed dead rats in his shop, and later both he and his son died from the disease in another part of the town in which they resided. Cases next appeared in the immediate neighbourhood of the shop. The shopkeepers affected slept at night in various parts of the city and no doubt carried with them plague-infected fleas; then shortly afterwards a large number of rats dying from plague were observed and next a number of human cases were noted. The disease lasted from the beginning of April to the end of July, when it died out entirely. The death-rate in Peshawar from plague was at the rate of 89·2 per cent. owing to the disinclination of the people to report cases; the number was certainly larger than the plague returns showed. With respect to treatment, 534 persons were inoculated with excellent results; in only one case did the disease occur and this was contracted in a very mild form and a rapid recovery was make. The people showed no violent opposition to the operation, but with the abatement of the disease they reverted to a condition of apathy regarding it. Much credit was due to the excellent work done by Captain E. C. Hepper, I.M.S., the special plague officer at Peshawar. The people were greatly excited by absurd rumours as to the poisoning of wells, resulting in a feeling of utter distrust often reaching [illegible] English medical men. Captain [illegible] good temper gradually restored [illegible] at were undertaken.

[illegible] cholera gave 266 deaths during [illegible] suspicious case of vomiting and purging occurred in the person of a stranger who came from down country to a village in the Kohat district. His clothes were washed in a nullah, and a few days afterwards several cases of the disease occurred in a village farther down the [illegible] drinking [illegible] es of the [illegible] recorded [illegible] ath-rate [illegible] aria and [illegible] Small-[illegible] 27 of the previous year. In the city of Peshawar, which is one of the towns in the province where the Vaccination Act has not been brought into force, a death-rate of 0·80 per 1000 was recorded. The highest death-rate, 3·29, was given by the town of Buffa; this is very unsatisfactory, as the Vaccination Act was brought into force in this town in May, 1906, and the natural inference is that the provisions of the Act were not rigorously enforced. Dysentery and diarrhœa [illegible] emained much the same as in previous years, as usual the [illegible] atio being highest in the Dera Ismáil Khan district, where the drinking water is as a rule very bad.

This report of Lieutenant-Colonel Dennys, although somewhat short, the text being limited to eight pages, is a model of conciseness, and reflects the greatest credit on the well-established reputation of this officer.

MEDICINE AND THE LAW.

A Medical Man's Claim for Fees against an Ambassador.

ON March 31st, in the Marylebone county court, his honour Judge Sir William Selfe had before him a claim for £10 17*s.* 6*d.* made by Dr. A. S. Currie of Oxford-terrace, Hyde Park, the defendant being General E. M. Terán, now residing at Alexandra-terrace, West Hampstead, who did not appear. When this claim was called before the registrar the defendant set up the defence of immunity from process on the ground that he was Envoy and Minister Plenipotentiary to this country from the Republic of Ecuador. The defendant's letters of recall had since that time been issued, and a letter from the Foreign Office was read stating that such letters of recall had been received, and adding that after their date General Terán could not claim immunity from process on account of his diplomatic position. It was contended for the plaintiff, on the authority of the case of Musurus Bey, decided in 1894, that the immunity was unconditionally removed for any period. Dr. Currie gave evidence that he had attended the defendant's children at his residence at Hampstead in May and June, 1907, and his fees amounted to the sum claimed. The judge inquired why the action was not brought earlier. The plaintiff replied that the claim was made, but the plea of immunity was set up, and he therefore decided to await the expiry of that position before coming to court. His honour gave judgment for the amount claimed with costs. Ambassadors and Ministers of foreign States hold a somewhat curious position. It would be impossible for an envoy efficiently to discharge the duties of his mission if his liberty of action was restrained like that of any other sojourner by obedience to the local jurisdiction. In order, [illegible] certain exemption from such jurisdiction. While such privilege continues the envoy remains subject to the laws of his own State which [illegible] property according [illegible] resident in a foreign [illegible] the territory of his own. Such is the nature of the fiction of exterritoriality invented to give intensity to the idea that the envoy, his family, and his suite are exempt from all local control. The exemption, which is supposed to rest upon a tacit compact between the sending and receiving State, begins the moment the envoy enters the territory of the latter, and continues not only during his entire residence but until he loses his official character or leaves the country, even when prior to his departure war has broken out between his own State and that to which he [illegible] ivilege continues it exempts the [illegible] le effects from the local jurisdic-[illegible] through him it is extended to those of his suite possessing a diplomatic character; and in a lesser degree to his wife, children, chaplain, private secretary, and servants, persons necessary to his comfort and convenience but not a part of the diplomatic corps of his country. An ambassador, having no real property in the country and having done nothing to disentitle him to the general privileges of [illegible] ambassador, be sued [illegible] suit may arise out of c[illegible] although neither his person nor his goods are touched by the suit. But if the ambassador appears and submits to the jurisdiction the action can then be proceeded with.

Looking Back.

SOCIETE DE PHARMACIE DE PARIS.

February 8th.

NEW METAL, VANADIUM.[1]

M. DULONG read a letter from M. Berzelius, announcing the discovery of this new metallic substance. M. Selstrom, director of the mining school at Fahlun, in the examination of a specimen of iron remarkable for its extreme softness, recognised in it the presence of a substance, the properties of which are different from those of all bodies hitherto described. The quantity contained in the specimen first examined was so small as to prevent a successful inquiry into its nature. The iron was brought from the mine of Taberg, in Smoland, and M. Selstrom having found that the smelting furnace contained a greater quantity of the new substance than the iron did, and that the scoriæ were still more richly impregnated with it, a sufficient quantity was procured and examined conjointly by MM. Berzelius and Selstrom.

It is provisionally termed Vanadium, from Vanade, the name of a Scandinavian divinity. Vanadium forms with oxygen two compounds, an oxide and an acid. The acid is red, pulverulent, fusible, and crystalizable after fusion as it cools. It is slightly soluble in water, reddens turnsole, affords yellow neutral, and orange supersalts. The acid and basic combinations which it forms, possess in solution the singular property of frequently becoming colourless in a moment, and they resume their colour when again solidified. Hydrogen gas reduces vanadic acid to a reddish-white colour, there remaining a coherent mass of a weak metallic splendour, and an excellent conductor of electricity. The vanadium thus obtained combines only with sulphur, when heated to redness in an atmosphere of the vapour of that substance. The oxide of vanadium is brown, nearly black, and dissolves readily in acids. Its salts are of a deep-brown colour, but by the addition of a little nitric acid, effervescence takes place, and the colour becomes a beautiful blue. Sulphuretted hydrogen, and even nitrous acid, reduce the vanadic acid when in combination with any other acid to this blue matter, which appears to be a compound of the oxide of vanadium and vanadic acid analogous to the compounds formed by molybdenum, tungsten, iridium, and osmium. The acid and oxide of vanadium combine with each other, forming green, yellow, and red compounds, soluble in water, without the aid of any other acid.

---

[1] It subsequently appeared that this substance was first found in a [illegible] in Mexico in the year 1801, by Del Rio, who [illegible]

The oxide of vanadium when obtained, *viâ humidâ*, is soluble in water and alkalies. The presence of a salt in the water entirely prevents the solution, and we thus obtain a mode of precipitating oxide of vanadium, by adding to its solutions any neutral salt.

The vanadates dissolved in water are decomposed by sulphuretted hydrogen, being transformed into sulpho-salts of a beautiful red colour. The chloride of vanadium is a colourless liquid, exceedingly volatile, and producing a dense red vapour. The fluoride is sometimes colourless, sometimes red, but always fixed in the air. Before the blowpipe, vanadium colours the fluxes a beautiful green, like chrome.—*Journal de Pharmacie, Mars, 1831.*

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Richmond.—Dr. J. H. Crocker devotes some space in his report to a consideration of the question as to whether intercepting traps between the sewer and the house should continue to be provided and whether their presence can be safely dispensed with. As is well known, there is considerable difference of opinion amongst sanitary engineers as to the value of these traps, those who disapprove of them holding that the frequency with which they become stopped up more than counterbalances any advantages which they possess. A number of these traps have been inspected in Richmond and a certain number of them showed evidence of having been recently stopped up, but in only one instance was the "cap" over the "raking" arm not in position. It appears to be generally conceded that in old properties, where the process of properly ventilating the sewers by the house drains would have to be gradual, there is considerable objection to the proposed alteration, as theoretically there would be accentuated stress put upon the ventilators which were placed in direct communication with the sewers. There is, too, the objection that in old properties the drains are frequently defective and that in cases where, as in town, the drains pass beneath the house the chances of the influx of sewer air would not be negligible. The problem is materially complicated by the fact that the sewer must be ventilated somehow and that this frequently necessitates the erection of a sewer ventilator on a house. But in these cases there is no chance of insuction of sewer air, as would undoubtedly be the case were each house drain ventilator also a sewer ventilator. Water-closets may become unsyphoned in so many ways and house drains so frequently become defective that many persons would hesitate before placing their house drains in direct communication with the sewer air. If an intercepting trap becomes obstructed and drain air enters the house the inhabitants are dealing only with such infections as they already possess, whereas, when there is no such trap they may be dealing with the common sewer air, which, as we now know, is capable under certain conditions of transmitting micro-organisms. It is obviously a very difficult matter to actually demonstrate the relative dangers associated with one or another system, but it is not improbable, having regard to the defects to which drains and sewers are liable under existing conditions of construction and want of supervision, that some medical officers of health would be unwilling to part with the trap which can be controlled and which will, if controlled, guard against invasion of micro-organisms from sewer air. Dr. Crocker thinks that in laying out new districts the intercepting trap might be dispensed with, provided, of course, that sewers and drains were practically perfect, but he does not think that the use of the traps can be dispensed with in existing properties. The question is under the consideration of the Local Government Board, and perhaps some pronouncement upon the subject may be anticipated.

County Borough of Southport.—Mr. John J. Weaver estimates the population of this important Lancashire health resort at 53,318, a number which is, we imagine, greatly augmented during the summer months. The birth-rate for 1908 was 16·84 per 1000, the death-rate (exclusive of visitors) 11·35 per 1000, and the infantile mortality 104 per 1000 registered births. The experience of Southport in the matter of "return" cases of scarlet fever is interesting so far as it goes. A discharging block was erected a few years ago and subsequently the number of "return" cases appeared to increase, and this increase, it is thought, may have been due to the setting up of catarrhal conditions due to the sudden change from artificially heated wards to the conditions of the average home. Consequently, endeavours have been made to render the change less sudden and the temperature of the final bath has been lowered, with the result, it is believed, of a diminished number of "return" cases. But these numbers are small and, as Mr. Weaver evidently feels, it is necessary to speak with caution on the subject. Still, up to two years ago, the "return" cases amounted to rather over 5 per cent. of the total, whereas since then they have been reduced to a little under 1 per cent. Mr. Weaver made a report to the education committee relative to the medical inspection of school children, in which he advised the appointment of an assistant medical officer of health who should perform the inspections, and of a nurse who should act both as regards school work and infantile mortality, but the council has apparently decided to keep the duties of the school officer distinct from those of the health department. New sewage works have recently been erected, consisting of sedimentation tanks and bacterial filters, the effluent passing out into the estuary of the Ribble. As regards the sewers themselves, the surface ventilators were closed some years ago and ventilation provided for by ventilating lamps. Coincidently with the adoption of the policy there has been a great diminution in the notifications and deaths from enteric fever. The analysis of certain foods in this district has yielded some rather striking results. In certain sausages boric acid to the extent of 38·2 grains per pound was found, while some potted shrimps, for which Southport is famous, contained 58·15 grains of boric acid per pound. One sample of "potted lobster" was found to contain no lobster, and another 27·7 grains of boric acid. Two samples of fish paste with lobster contained 56·44 and 43·4 grains of boric acid per pound respectively, and two samples of potted shrimp and salmon yielded respectively 63·3 and 67·7 grains per pound of boric acid. *All these latter cases were dismissed!*

Woodford Urban District.—The Notification of Births Act was adopted in this district only after considerable opposition at the hands both of the ratepayers and the medical profession, and a similar hostility appears to have been encountered at the appointment of a health visitor. But the health visitor obtained a better appointment after ten months' work in the district, and although Mr. W. G. Groves, the medical officer of health, reported that the results of her work and of the Notification of Births Act were satisfactory and promising, the district council when appointing another health visitor decided not to insist on early notification of births. The medical officer of health is naturally disappointed at this, as he regards the two provisions as largely interdependent. Mr. Groves states that in his view the effect of isolation hospitals in preventing the spread of infectious diseases has been less than was anticipated. This opinion appears to be becoming fairly general amongst medical officers of health. The medical inspection of school children in this district is carried out by medical officers appointed by the Essex county council.

Borough of Tunbridge Wells.—Mr. William Stamford reports that the town council has had under consideration the medical inspection of school children and has formed an elementary school medical department for the borough. This is to consist of the medical officer of health, three medical officers, and a nurse. The medical officer of health is to supervise generally and to report to the education committee and the Board of Education; the three medical officers are to conduct the correspondence, to examine the children, and to prepare returns for transmission to the medical officer of health; while the nurse is to attend on the medical officers, to follow up cases where necessary, and generally to carry out the instructions of the medical officers.

Borough of Guildford.—There was an outbreak of scarlet fever in this town in January, 1908, which was believed by

Dr. R. W. C. Pierce to have been probably caused by a girl, daughter of a cowman, having indirectly infected the milk-supply. This girl had been isolated in a fever hospital in another part of the country while suffering from diphtheria, and during her stay at the hospital she developed a rash which was ascribed to antitoxin, but which may, it seems, have been a scarlet fever eruption. It is possible, however, that the milk may have been infected by another man in contact with the milk, one of whose children had suffered from illness with a rash some three weeks previously. The fact has also to be mentioned that one of the cows had an eruption on its teats. On excluding both the men in question, as also the milk of the affected cow, the milk at once ceased to spread disease. There were seven instances of "return" cases of scarlet fever during the year under notice, and nearly all were associated either with recurrent nasal discharge or enlarged tonsils and adenoids. One child had been in hospital nearly 19 weeks. In 1906 18 cottages were built by the council and all of them were occupied throughout 1908 at rentals of 6*s.* 6*d.* and 7*s.* 6*d.* per week. The question of adopting the Notification of Births Act was considered by the council, but having regard to the low infantile mortality rate (73 per 1000 births) it was not thought desirable to incur the expense. Moreover, the Guildford division of the British Medical Association objected to the adoption of the Act owing to there being no fee attached to notification.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN: ANNUAL REPORTS OF MEDICAL OFFICERS.

Berkshire Education Committee.—Dr. Gerard O. Taylor, who is county medical officer of health as well as school medical officer, in presenting his first annual report in his latter capacity, states that as regards school closure in outbreaks of measles or whooping-cough the usual practice has been to close an infant department when either of the diseases is prevalent in the neighbourhood and the attendance has already been seriously affected; but he expresses a doubt whether, in view of the opportunities for infection outside the school, closure even at an early stage of an epidemic is of much benefit in checking the spread of the malady. With respect to the sanitary condition of schools, Dr. Taylor reports that when no sewers are available earth-closets are being gradually substituted for privy-pits and cesspools, the pail contents being buried daily in shallow trenches and the waste water collected in a small tank, from which it is pumped each evening and disposed of by surface irrigation. The total population of the administrative county is estimated at about 141,300 and the number of school children at 24,500. Unless children are practically five years old they are not admitted to school. The schools of the county have for purposes of inspection been divided into two groups, one group being assigned to each of the two assistant medical officers. There are as yet no school nurses, and their absence is felt administratively. 3144 children have been examined and of these 12·7 per cent. were reported to be free from disease or defect, while it was found necessary to give directions to the parents or guardians of 84 per cent. of the children examined. 2 per cent. were found to be insufficiently clothed, pediculi or nits were found in the hair of 22 per cent., and 55 per cent. had defective teeth. *As regards defective teeth, it is reported* that an altruistic dental surgeon at Abingdon has offered to treat gratuitously cases sent to him by the parents. Here there is one of the great problems of medical treatment already [illegible] solution [illegible] and 21 [illegible] children whose vision was tested, 73·9 per cent. were normal as regards both eyes. *25 children were mentally defective,* and use has been made of the Defective and Epileptic Children Act, which has been adopted in the county. Very few cases of lung disease were found. There were one case of pulmonary tuberculosis and 51 instances of enlarged thyroid.

East Suffolk Education Committee.—Dr. George I. T. Stewart, in describing the method of inspection adopted, reports that the mouths and throats of the children are examined by means of a gardener's wooden label five inches long, one label being used for each child. The presence or absence of adenoids in the naso-pharynx is estimated by the general condition of the child as to the shape of the mouth and chest, the condition of the tonsils, and the frequency of bronchitic attacks, *digital examination for the presence of* these growths being made only in difficult cases and with the consent of the parents. This is probably a wise precaution at the first examination, as any infliction of pain upon the children would be likely to lead to a loss of confidence and perhaps opposition to inspection. Dr. Stewart has, for instance, found that the information obtained is greater when the inspection is conducted with several children present in the room, as in this fashion the children see that no pain is inflicted. Actual objection to medical inspection is evinced, the report states, by two classes. In the first place, there are the comparatively well-to-do parents who resent official interference on the ground that they have a medical attendant of their own; in the second place, there are the parents of neglected children who dread *what medical inspection may reveal.* There have been 4222 children examined. In 120 cases nutrition was below normal; in 21 per cent. there were pediculi. In 2605 cases there was dental caries and in 1537 there were enlarged *tonsils or adenoids. Operations for these defects are,* Dr. Stewart reports, rare owing to the belief that the children will "grow out" of the defects, and he states that children attend school irregularly more frequently from constantly *recurring attacks of tonsillitis and bronchitis than from any other cause.* Enlarged thyroid was found in 10 cases and defective hearing in 178 cases. There was some defect of speech in 48 cases, and in 43 additional instances *defect of speech was found to be due to deficient use* of the muscles of the lip, cheeks, and tongue, leading to slovenly partial guttural utterance. In many cases where the children showed indistinctness of articulation it was found that the mother owing to oral sepsis, lack of teeth, or a badly fitting plate was the cause of the child's defects by unconscious mimicry. Of 150 children examined as to their mental condition it was found that a third would improve more rapidly if instructed at a special school where manual training forms an essential element in teaching, and Dr. Stewart thinks that it would be well to provide for them a forest or garden colony. Chronic bronchitis has been found to affect school attendances very largely, [illegible] malady lead to a belief that th[illegible] But Dr. Stewart found no signs [illegible] cases which were examined.

Borough of Guildford Education Authority.—Dr. R. W. C. Pierce, whose report as medical officer of health of this borough is dealt with in another column, reports that as the air in several of the schools produces the impression of "stuffiness" to one entering from the fresh air, he proposes to estimate the amount of carbonic acid gas as a means of ascertaining the impurities, and he finds that many of the class-rooms have permanent means of ventilation on one side only. He has advised that all the Tobin's tubes should be periodically cleansed. The lighting in several of the schools is defective, and arrangements for drying the cloaks and coats of the children are found in a few schools only. (We wonder whether such provisions are to be found in many of the schools for the richer classes.) The actual medical inspection of the children is carried out by a medical inspector, who reports direct to the school medical officer, Dr. Pierce; no school nurse has yet been appointed. *No treatment has been undertaken by the education committee,* and the services of the usual medical adviser or attendance at the county hospital has apparently sufficed, *except in the case of ringworm and skin diseases, for which affections it is the practice of the parents to seek relief from* the druggists or to use some domestic nostrum which is valueless. Clearly the appointment of a school nurse is called for.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8524 births and 5397 deaths were registered during the week ending April 17th. The annual rate of mortality in these towns, which had declined from 22·1 to 17·0 per 1000 in the five preceding weeks, rose again to 17·1 in the week under notice. During the 13 weeks of last quarter the death-rate averaged 18·8 per 1000, while in London during the same period the mean rate was 19·6. The lowest recorded annual death-rates in these towns last week were 8·3 in King's Norton, 8·9 in Leyton, 10·4 in Hornsey, and 10·7 in Willesden; the rates in the other towns ranged upwards to 23·3 in Oldham, 24·8 in Bootle, 27·1 in Tynemouth, and 28·3 in Great Yarmouth. In London the recorded death-rate during the same week was equal to 17·3 per 1000. The 5397 deaths from all causes in the 76 towns last week showed an increase of 33 over the number in the preceding week, and included 584 which were referred to the principal epidemic diseases, against 573 and 593 in the two preceding weeks; of these 584 deaths, 321 resulted from measles, 130 from whooping-cough, 47 from diphtheria, 40 from diarrhœa, 31 from scarlet fever, and 15 from "fever" (principally enteric), but not any from small-pox. The 584 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·9 per 1000, against 1·8 and 1·9 in the two preceding weeks; in London the recorded rate from these diseases was equal to 2·1 per 1000. No death from any of these epidemic diseases was registered last week in Gateshead, Birkenhead, Halifax, Northampton, Huddersfield, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, in the other towns to 3·7 in Smethwick, 5·3 in Bootle, 6·5 in Warrington, and 6·6 in St. Helens. The fatal cases of measles in the 76 towns, which had declined from 438 to 327 in the four preceding weeks, further fell to 321 in the week under notice, but caused death-rates ranging upwards to 3·0 in Sheffield, 3·6 in Warrington, 3·7 in Smethwick, 5·3 in Bootle, and 6·0 in St. Helens. The deaths from whooping-cough, which had been 103 and 107 in the two preceding weeks, further rose last week to 130 and exceeded the number in any previous week of the year; the highest death-rates from this disease in the week under notice were 1·3 in Croydon, 2·6 in Preston, and 2·9 in Grimsby. The 47 fatal cases of diphtheria showed a decline from recent weekly numbers, and included 16 in London and its suburban districts, five in Manchester, three in Rhondda, and two each in Southampton and Stockport. The 40 deaths from diarrhœa slightly exceeded the number in the previous week, and caused death-rates to 1·2 in Aston Manor and 1·5 in Burnley. The fatal cases of scarlet fever, which had been 41 and 47 in the two preceding weeks, declined again to 31 in the week under notice, the highest death-rates from this cause being 1·4 in Warrington. The 15 deaths referred to "fever" showed a decline of seven from the number in the preceding week, and included three each in London and in Liverpool, and two each in Southampton and in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 2873 to 2418 at the end of the six preceding weeks, had further decreased to 2294 on Saturday, April 17th; 244 new cases were admitted during the week, against 327, 273, and 256 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had decreased from 758 to 310 in the five preceding weeks, rose again to 341 in the week under notice, and exceeded by 16 the corrected average number in the corresponding week of the five years 1904–08. The deaths in London directly referred to influenza, which had been 137, 108, and 62 in the three preceding weeks, further fell to 43, but were 16 above the corrected average number. The causes of 52, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, Nottingham, Leicester, Salford, and in 47 other smaller towns; the 52 uncertified deaths included 11 in Birmingham, 11 in Liverpool, and four in Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had declined from 21·6 to 17·7 per 1000 in the five preceding weeks, rose again to 18·4 in the week ending April 17th. During the 13 weeks of last quarter the annual death-rate in these eight towns averaged 19·5 per 1000, and exceeded by 0·7 per 1000 the rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates in the week under notice ranged from 8·5 in Leith and 17·5 in Aberdeen to 19·4 in Dundee and 22·0 in Perth. The 656 deaths from all causes registered in the eight towns last week showed an increase of 22 over the number in the preceding week, and included 98 which were referred to the principal epidemic diseases, against 78 and 90 in the two preceding weeks; of these 98 deaths, 58 resulted from whooping-cough, 18 from diarrhœa, seven from diphtheria, six from scarlet fever, five from measles, and four from enteric fever, but not any from small-pox. These 98 deaths from epidemic diseases were equal to an annual rate of 2·7 per 1000, which was 0·8 per 1000 above the mean rate during the same week from these diseases in the 76 English towns. The fatal cases of whooping-cough in the eight Scotch towns, which had been 47 and 55 in the two preceding weeks, further rose to 58 in the week under notice, and included 44 in Glasgow, five in Edinburgh, four in Greenock, two in Paisley, and two in Perth. The deaths from diarrhœa, which had been 14 and 13 in the two preceding weeks, rose again last week to 18, of which 11 occurred in Glasgow and five in Aberdeen. The fatal cases of diphtheria, which had been six and nine in the two previous weeks, declined again to seven last week, and included four in Glasgow and two in Paisley. The deaths from scarlet fever, which had declined from six to three in the four preceding weeks, rose again to six in the week under notice, and included four in Glasgow. The five fatal cases of measles exceeded the numbers in other recent weeks, and included four in Paisley. The four deaths from enteric fever corresponded with the number in the previous week and were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had declined from 187 to 108 in the four preceding weeks, rose again to 135 in the week under notice, and were 14 in excess of the number in the corresponding period of last year. The causes of 16, or 2·4 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had declined from 29·3 to 25·5 per 1000 in the four preceding weeks, rose again to 27·7 in the week ending April 17th. During the 13 weeks of last quarter the death-rate averaged 25·7 per 1000, whereas the mean rate during the same period did not exceed 19·6 in London and 18·1 in Edinburgh. The 212 deaths of Dublin residents from all causes during the week under notice exceeded by 17 the number in the preceding week, and included 21 which were referred to the principal epidemic diseases, against 20 and 17 in the two preceding weeks. These 21 deaths were equal to an annual rate of 2·7 per 1000, the rate from the epidemic diseases during the same week being 2·1 in London and 0·9 in Edinburgh. Of the 21 deaths from these epidemic diseases in Dublin last week, 11 resulted from whooping-cough, five from measles, two from diarrhœa, and one each from scarlet fever, diphtheria, and "fever," but not any from small-pox; the deaths from whooping-cough exceeded the number in any previous week of the year, while those from measles showed a slight decline from recent weekly numbers. The 212 deaths registered during the week included 37 of infants under one year of age and 60 of persons aged upwards of 60 years, these numbers being respectively two below and eight above the corresponding numbers in the previous week. Six inquest cases and four deaths from violence were registered; and 72, or 34·0 per cent., of the deaths occurred in public institutions. The causes of five, or 2·4 per cent., of the deaths in Dublin last week were not certified either by a registered medical practitioner or by a coroner; in London all but two of the 1606 deaths were duly certified, while in Edinburgh the causes of 2·5 per cent. of the deaths were uncertified.

VITAL STATISTICS OF LONDON DURING MARCH, 1909

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1909	NOTIFIED CASES OF INFECTIOUS DISEASE											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES											Deaths from all causes	Death rate per 1000 living	Deaths of infants under one year to 1000 births

* Including membranous croup

that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·9 per 1000 of the population, estimated at 4,833,938 persons in the middle of the year; in the three preceding months the rates were 7·6, 7·2, and 6·4 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hammersmith, Hampstead, Holborn, and Lambeth; and the highest rates in Chelsea, Shoreditch, Stepney, Poplar, Deptford, Lewisham, and Woolwich. The five cases of small-pox exceeded the numbers notified in other recent months and belonged respectively to the City of Westminster, Hampstead, Holborn, Southwark, and Lewisham. Scarlet fever continued to show a declining prevalence last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Chelsea, Stoke Newington, Stepney, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals,. which had been 3498, 3147, and 2766 at the end of the three preceding months, had further declined to 2412 at the end of last month; the weekly admissions averaged 278, against 371, 343, and 283 in the three preceding months. Diphtheria was slightly less prevalent during March than in either of, the two preceding months; the greatest proportional prevalence of this disease was recorded in Fulham, Shoreditch, Stepney, Southwark, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 1103 diphtheria patients at the end of last month, against 953, 1182, and 1152 at the end of the three preceding months; the weekly admissions averaged 121, against 143, 136, and 133 in the three preceding months. Enteric fever was again less prevalent than in other recent months; the greatest proportional prevalence of this disease last month was recorded in Kensington, St. Marylebone, Islington, Stoke Newington, Holborn, Bethnal Green, and Wandsworth. The Metropolitan Asylums Hospitals contained 87 enteric fever patients at the end of last month, against 147, 126, and 124 at the end of the three preceding months; the weekly admissions averaged nine, against 16, 18, and 17 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Bethnal Green, Stepney, Southwark, and Bermondsey. The 23 cases of puerperal fever notified during the month included three each in Fulham, St. Pancras, and Islington, and two each in Stoke Newington, Lambeth, and Battersea. The 24 cases notified as cerebro-spinal meningitis included four each in Southwark and Lambeth, and two each in St. Marylebone, Islington, Bethnal Green, and Poplar.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending April 3rd the deaths of 9919 persons belonging to London were registered, equal to an annual rate of 21·4 per 1000; in the three preceding months the rates were 14·3, 16·4, and 18·5 respectively. The death-rates last month ranged from 11·8 in Hampstead, 14·2 in Lewisham, 16·3 in Greenwich, 16·6 in Fulham, 17·0 in Woolwich, and 18·0 in Hackney, to 25·3 in Southwark, 25·9 in Chelsea, 28·3 in Bermondsey, 28·4 in Shoreditch, 29·1 in Finsbury, and 29·2 in the City of London. The 9919 deaths from all causes included 933 which were referred to the principal infectious diseases; of these, one resulted from small-pox, 533 from measles, 40 from scarlet fever, 85 from diphtheria, 198 from whooping-cough, 17 from enteric fever and 59 from diarrhœa, but not any from typhus fever or from ill-defined pyrexia. The lowest death-rates from these diseases were recorded last month in Paddington, the City of Westminster, Hampstead, Holborn, Greenwich, and Lewisham; and the highest rates in St. Pancras, Islington, Shoreditch, Southwark, Bermondsey, Battersea, and Wandsworth. The 533 fatal cases of measles were as many as 293 above the corrected average number for the corresponding period of the five preceding years; the greatest proportional mortality from this disease last month occurred in St. Pancras, Islington, Shoreditch, Southwark, Bermondsey, and Wandsworth. The 40 deaths from scarlet fever were four fewer than the corrected average; of these 40 deaths, six occurred in Stepney, and three each in St. Pancras, Islington, Bethnal Green, Poplar, and Lambeth. The 85 fatal cases of diphtheria exceeded the corrected average number by ten; the highest death-rates from this disease last month were recorded in Kensington, Fulham, Chelsea, St. Shoreditch, and Woolwich. The 198 deaths from cough were 18 below the corrected average number corresponding period of the five preceding years; the proportional mortality from this disease occurred in Newington, Finsbury, Shoreditch, Bermondsey, Battersea. The 17 fatal cases of enteric fever were the corrected average number,; these 17 deaths included in Islington, two in Bermondsey, and two in Lambeth. The 59 deaths from diarrhœa showed a decline of 12 the corrected average number; this disease was tionally most fatal in St. Pancras, Shoreditch, Poplar, Southwark, and Lewisham. The fatal case of pox belonged to the City of Westminster. In it may be stated that the aggregate mortality in last month from these principal infectious diseases was per cent. above the average.

Infant mortality, measured by the proportion of among children under one year of age to registered was equal to 120 per 1000. The lowest rates of mortality were recorded in St. Marylebone, Stoke Holborn, the City of London, Lewisham, and W and the highest rates in Hammersmith, Islington, Poplar, Southwark, Bermondsey, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon G. T. Collingwood to the *Racer*, additional, for Royal College, Osborne; J. Sugrue to the *President*, additional, Royal Marines, Recruiting Headquarters; J. Lloyd-Thomas the *Eagle;* W. E. Home to the *Dædalus;* P. M. Maye to *Vengeance* and to the *Trafalgar*, on becoming parent ship C. J. Mansfield to the *Formidable*, on commissioning. Staff Surgeons: E. Folliott to the *Forte;* C. B. Fairbank to the *Victorious*, on recommissioning; E. T. Burton to the *Egmont*, additional, for Malta Dockyard; and W. K. Hopkins to the *Talbot*, on recommissioning. Surgeons: E. R. L. to the *Crescent*, additional, for the *Edgar*, temporarily; G. D. Bateman to the *Formidable*, on commissioning; G. Bradshaw to the *Hindustan;* R. Kennedy to the *Forte*, completing; and L. M. Morris to the *Blenheim*, temporarily

ROYAL ARMY MEDICAL CORPS.

Surgeon-Major Samuel G. Moores, from the Scots Guards to be Major (dated April 17th, 1909).

Lieutenant-Colonel R. I. D. Hackett and Lieutenant-Colonel H. I. Barrett will exchange positions on the foreign service roster. Captain J. B. Meldon, from Bangalore, has been appointed to the Dublin District. Major C. C. Fleming D.S.O., will take up the appointment of instructor at the Royal Army Medical Corps School, Aldershot, in June, Major J. D. Ferguson, D.S.O.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Northern General Hospital: Surgeon-Captain Arthur Longley Whitehead, from the 1st West Riding Brigade Royal Field Artillery, to be Captain and to be an officer whose services will be available on mobilisation, retaining his seniority as in the Royal Field Artillery, Territorial Force (dated Feb. 25th, 1909).

For attachment to Units other than Medical Units.—Major John W. Ellis to be Lieutenant-Colonel (dated June 15th, 1908). Thomas Hillhouse Livingstone to be Lieutenant (dated March 1st, 1909). Cecil Johnson to be Lieutenant (dated March 23rd, 1909.

THE ALEXANDER MEMORIAL PRIZE.

The Alexander Memorial Prize, consisting of £50 and a gold medal, is awarded every third year to the writer of the best essay on a subject connected with military medicine, surgery, or hygiene. The competition is open to executive officers of the Royal Army Medical Corps on full pay, with the exception of the professors and assistant professors of the Royal Army Medical College during their period of office. No prize has been awarded for the triennial period ending Dec. 31st, 1908. The subject for the next prize essay is the following: "Tropical Abscess of the Liver." The subject may be treated either from a clinical or etiological standpoint and the essay must bear evidence of original observations. No essays should exceed 20,000 words, exclusive of tables, which may be added as appendices. Essays should be sent in to the secretary of the Prizes Committee, Royal Army Medical College, on or before Dec. 31st, 1911. Each essay is to have a motto and to be accompanied by a sealed envelope bearing the same motto and containing the name of the competitor.

SANITARY SERVICE (R.A.M.C.) DINNER.

The officers of the Sanitary Service of the Royal Army Medical Corps will dine at the Hôtel Métropole on Saturday, May 8th. The Right Hon. R. B. Haldane, M.P., Secretary of State for War; General Sir W. G. Nicholson, Chief of the General Staff: Surgeon-General Sir A. H. Keogh, Director-General, A.M.S.; and Lieutenant-General Sir W. H. Mackinnon, Director-General of the Territorial Forces, are the guests.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on April 20th, Sir O. J. Thomas, K.C.B., in the chair, the sum of £55 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

AN AMBULANCE SERVICE FOR THE METROPOLIS.

To the Editor of THE LANCET.

SIR,—May I be permitted, as having had some considerable acquaintance with this subject, to endorse the plea in your leading article that to medical men the great thing at present is action by the Home Office in some direction. During 21 years' service as one of the divisional surgeons to the Metropolitan Police I had ample opportunities of seeing the need for such a service, having been obliged, sometimes at night, to send patients with broken limbs three or four miles to Guy's or St. Thomas's Hospitals in a four-wheeler—not exactly an ideal conveyance for a suffering patient.

Personally I must confess that I am unable to see how the coöperation of either the Metropolitan Asylums Board or the London County Council is essential. All the Metropolitan force as they join the ranks are now, I am informed, trained to render first aid, and on the occurrence of illness or accident in the streets they are authorised and directed to call in the nearest medical man to their aid if the divisional surgeon should be too far off. Liverpool has for a number of years had an admirable ambulance service organised by the police alone, and in recent years Captain Nott-Bower, who had experience of the Liverpool system before he was appointed Commissioner of the City of London Police, has got a similar service into working order there. What Liverpool and the City have done, Scotland Yard might surely be trusted to do with two such excellent models before it if only the Home Office would authorise the purchase of ambulances.

I am, Sir, yours faithfully,

H. NELSON HARDY,

President, United Kingdom Police Surgeons' Association.

London, April 19th, 1909.

THE ETIOLOGY OF ACNE.

To the Editor of THE LANCET.

SIR,—May I trespass upon your space for some remarks on Dr. A. Fleming's valuable paper on the etiology of acne in your issue of April 10th? Dr. Fleming's contention that the micro-bacillus is the cause not only of the comedo but of the suppuration of acne is based on the following reasons: (1) it is constantly present in the films made from the pus; (2) it is frequently the only organism present in the pus; (3) it can frequently be recovered from the pus in pure culture; (4) inoculated into a susceptible individual it produced a pustular folliculitis, and examination of the pus showed no other organisms to be present; (5) inoculated into animals it produces an abscess from which the bacillus has been recovered in pure culture (Gilchrist); (6) the serum of patients affected with acne agglutinates the bacillus in some cases; (7) the opsonic indices of patients to the acne bacillus vary considerably from the normal; (8) large doses of a vaccine made from the acne bacillus induce a marked negative phase characterised by the appearance of fresh pustules from which the organism has been recovered in pure culture; (9) a vaccine of this organism has a marked beneficial effect on the condition; and (10) when a patient has a high opsonic index to the bacillus his condition improves, but when the opsonic index is low fresh pustules appear.

Now these results appear at first sight to be sufficient proof of the causal relationship of the bacillus to the suppuration of acne, but careful consideration will, I think, throw some doubt upon this conclusion. I may begin by quoting again a valuable principle laid down by Sabouraud—namely, that where an organism is found in luxuriant growth in the skin, that organism is producing its noxious effects, if any. I think it is sufficiently obvious that we must either admit the validity of this statement or throw overboard bacteriology in pathological research. Now it is admitted by all that if we examine the comedo in its *non-inflamed* state we find the micro-bacillus present in the most luxuriant growth. I have never examined a comedo without finding this (putting aside the grouped comedo of infants), and I have therefore agreed with Sabouraud that the micro-bacillus is the cause of the comedo. Acting as a mild irritant to the neck of the follicle it causes repeated attempts to be made by the epithelium to encyst it with the resultant characteristic onion-like formation. So far I think Dr. Fleming will agree with me.

Now as regards the suppuration it might be contended that only in certain persons is the micro-bacillus a pyogenic organism, but this is not the correct explanation for the following reason. If we take comedones surrounded by *no* inflammatory or pustular reaction from patients the subject of pustular acne we find this abundant growth of the micro-bacillus present in the non-inflamed comedo. So that we are driven, if we accept the pyogenic nature of the micro-bacillus, to say not that it is pyogenic in some persons, but that it is pyogenic in some lesions.

Years ago when working at this subject I examined a very large number of acne lesions both by the film method and by sections, and I came to the conclusions expressed in my book and quoted by Dr. Fleming. I have also examined for some years the pus from all private cases of acne and have only on very few occasions failed to demonstrate the staphylococcus in films. Recently I had a case in which I found no staphylococci present in films, but on excising a pustule I found them present in colonies near the wall of the little abscess. By cutting horizontal sections in this case I was able to demonstrate in one section two follicles so close together that both could be seen in one field of a one-inch objective, one suppurating with a central comedo and micro-bacilli and staphylococci in the pus when viewed with a high power, the other without the slightest leucocytic or other inflammatory reaction yet stuffed with micro-bacilli.

Turning now to Dr. Fleming's reasons, Numbers 1, 6, 7, 8, 9, 10 agree equally well with the bacillus as a cause of comedo. As regards 8, the causation of pustulation by the injection of bacillary vaccine, I have turned an ordinary microsporon ringworm of the scalp into a kerion on more than one occasion by the injection of ringworm vaccine, and am inclined to think that there is a future for this as a method of cure. Statement number two, that the bacillus is frequently the only organism present in the pus, I am convinced from an extremely extensive experience is inaccurate. The position of the staphylococci in the pus nearest the wall may account for the cultivation of the bacillus in pure culture on some occasions, and it is to be remembered that the suppuration is very indolent as a rule and that there are comparatively few staphylococci present. In the more actively suppurating lesions staphylococci are much more numerous. As regards animal experiment (No. 5), it is

staphylococcic vaccine the whole of the suppuration had disappeared, leaving his face studded with non-inflamed comedones. The ultimate pathology of acne is, in my opinion, still unknown, and will probably be found to lie in some form of toxæmia, but I am convinced that it is a retrograde step to look upon it as a specific infective disease caused by this one very ubiquitous organism.

I am, Sir, yours faithfully,
April 14th, 1909. ARTHUR WHITFIELD.

AMPUTATION THROUGH THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—In the two cases of amputation through the hip-joint reported in THE LANCET of April 3rd by Mr. E. W. Roughton and Mr. T. P. Legg, I notice that the femoral artery and vein were first tied, but it is not stated whether any interval was made between the ligature of the artery and vein. In March of last year I had to operate at the Government Hospital for an enormous sarcoma of the femur. I first tied the femoral artery, and then, after an interval of about three minutes with the limb elevated, ligatured the vein. My idea was that the blood in the limb would thus to a great extent drain back into the patient's body and thus be instrumental in preventing shock. The same principle is involved in the use of the Esmarch bandage, but, of course, in a case of malignant disease this would be out of the question. Wyeth's pins were then introduced and the operation completed in the usual way. The pulse, which was 120 before operation, rose to 130 after completing the disarticulation. A saline and brandy enema was then administered, and before the patient left the theatre his pulse had sunk again to 118 and was of good volume and tension. From the point of view of shock, therefore, the operation was very satisfactory. The patient's recovery was rapid, the wound healing by primary union, but as he has never been seen since his discharge from hospital I cannot say whether recurrence ever took place. Mr. Legg says: "When amputation through the hip-joint is done for periosteal sarcoma of the femur the muscles should be cut as closely as possible to their pelvic attachments; this is impossible in Wyeth's method." This may be so, but I would venture to suggest that whatever method be adopted (direct abdominal pressure, Wyeth's pins, &c.) the blood in the limb should be first drained into the body in the manner I have indicated. The importance of ligating artery first and vein later after an interval may be well recognised by operating surgeons, but I do not think the point is sufficiently emphasised in the average text-book.

I am, Sir, yours faithfully,
A. WEBB JONES, F.R.C.S. Eng.,
Surgeon, Government Hospital, Alexandria.
Alexandria, Egypt, April 11th, 1909.

THE INTERNAL ANTISEPTIC TREATMENT OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—From time to time we find antiseptics given internally for various diseases, but no one, to the best of my knowledge, has ever advocated a systematic and universal use of the same. I will deal with the simple treatment of influenza. It has been stated by five or six eminent men that there is no preventive treatment for this disease. I find it impossible to agree with this, as proved in numerous cases and from personal experience. Quinine has been advocated, but it often fails. Failures are turned into successes if carbolic acid is given with it. This is a prescription which I think curative as well as preventive:—

℞ Quin. disulph. gr. ii.,
Ac. carbolic. (pur.), glycerini aa gr. iss.,
Ac. hydrobromic dil. ʒi.,
Tr. hydrast aquos ʒi.,
Aq. ad ℥viii. ft. mist

Sign. An eighth part three times a day, one hour after food. If case is severe every three hours, one hour after food.

No doubt the small dose of quinine will cause some to smile, but the old saying about "the proof of the pudding" applies in this case, and as this dosage has been given for so many years and in some thousands of cases with a death-rate of about 1 per 1000, I have excellent reason to believe in it. Moreover, large doses often defeat the end in view. Some lung cases, and those that have been weakened by salicylates, do better for a time with a prescription of ammon. carb., glycerine acid. carbolic., and tinctura cinchon. co. The old system of profuse sweating in influenza is most mischievous and often leads to lung complications and a long convalescence. Everyone is agreed that rest, warmth, and good, light, nourishing food, with fresh air, are correct treatment. I condemn strongly the use of salicylate of sodium or any other preparation of salicylic acid in influenza; they seem to relieve but at the expense of the bodily strength, especially the heart, and, as a rule, convalescence is prolonged after their use. Alcohol is injurious and can only be permitted sometimes and with careful watching in pneumonia after influenza. Nitrate of potash, vinum antimoniale, and tinctura aconiti are, in my opinion, drugs that ought to be consigned to the scrap-heap. The heart power must be kept up and it may be necessary to add strophanthus or digitalis to the mixture, but not in large doses. There are many patients with chronic debility after influenza who for months or even years have tried all sorts of tonics and change of air with very often but little improvement. I have seen many in Bournemouth and have found that the quinine mixture always puts them right in a short time. Special treatment is not required for the pains in the head and limbs in influenza, as the great point to bear in mind is that these varying symptoms are simply manifestations of one and the same toxin that has veritable protean possibilities, and must be eliminated by its proper antidote, which I have mentioned.

I am, Sir, yours faithfully,
Leeds, April 6th, 1909. F. W. CORY

*** Mr. Cory's note is intended to support the general use of antiseptics internally, but we doubt if the argument will be considered a very strong one. But a prescription which has proved of practical use has always some claims to publication.

THE PROXIMATE FACTOR OF DELIRIUM TREMENS.

To the Editor of THE LANCET.

SIR,—In his letter to THE LANCET of *April 17th*, Mr F. S. D. Hogg, referring to continuous and periodic drunkards, states that "the latter are just as liable *to suffer* from delirium tremens as are the former." I am loth to believe that this is a considered pronouncement on his part. It is not in accordance with generally received views, and it is entirely opposed to my own experience at the Norwood Sanatorium. In every case which occurred in that institution in past years, the patient was a continuous drinker; no purely periodic drunkard ever suffered. The majority were patients who rarely became intoxicated and then but slightly so; some had not been intoxicated for years. The latter are not, strictly speaking, drunkards at all; they have established a high grade of *tolerance of alcohol* and can only be said to suffer from chronic alcoholism. Such are strictly comparable to chronic morphinists, who, through long persistence in their habit, have eventually succeeded in establishing a high grade of tolerance of morphia, and the results of sudden withdrawal are in both cases analogous. Of course, there are chronic alcoholists who suffer from recurrent inebriety also, and these are equally prone to develop delirium on sudden withdrawal. But here the primary factor of the complication is the chronic, not the intermittently exaggerated, drinking. It is true, however, that a drunken outburst in one who habitually takes large quantities of alcohol without becoming intoxicated does often lead him, in a fit of remorse, to become suddenly an abstainer, and in such cases the drunken fit may properly be regarded as the *indirect* factor of the delirium. But even here the *proximate* factor is the sudden abstention.

I do not suppose that Mr. Hogg intentionally suggests that the occurrence of delirium tremens at Norwood in the past was due to ignorance on my part of the well-known sedative and hypnotic influence of the bromides and chloral hydrate. As a matter of fact, practically all the cases arose in spite of the prophylactic influence of such drugs, the frequent uselessness of which was peculiarly well shown on two occasions. Bromides in massive doses were given through the day and hypnotics at bedtime. As a result several hours' satisfactory sleep was obtained (six in one case, four in the other). Yet in both the patients awoke in wild delirium. On the other hand, since it has been the rule (a period of one and a half years) to taper off the alcohol *in patients who had established tolerance*, there has been no case of delirium, nor any which suggested a fear of that complicatio [illegible] tapering is carried out bromides and [illegible] called for.

The widely diverging views which obtain as to the expediency of sudden withdrawal are, I believe, reconcilable if we keep clearly in mind the full significance of tolerance. Tolerance of alcohol (i.e., acquired tolerance) implies intolerance of sudden withdrawal. It is not acquired through heavy intermittent drinking bouts, however frequent, but only through frequent regular drinking which stops short, often far short, of the intoxication point. Those who so drink inflict on themselves gross organic tissue changes, but they are not, as a rule, an intolerable nuisance to their friends or the general public Hence I do not believe that many such find their way into licensed retreats any more than they do into the police court.

I am, Sir, yours faithfully,

Upper Norwood, April 20th, 1909. FRANCIS HARE.

CROOKED QUESTIONS AND URBANE ANSWERS.

To the Editor of THE LANCET.

SIR,—The amiable reproof which *Punch* has administered to you in a recent issue for the promulgation of alarmist views is put into the mouth of a "Paterfamilias," who is understood to ask certain "plain, blunt questions." *To some of these, notwithstanding a know*ledge of the pitfalls which a cross-examiner is able to prepare for a witness, it should not be difficult to reply, and to show, contrary perhaps to expectation, that the interrogator is right to be anxious on the different points. It is asked, in the first place, whether cocoa causes cancer? If cocoa does not agree with "Paterfamilias," and he is of the age when cancer is most prevalent, he had better avoid it. A person who dislikes cocoa may say with perfect safety that it causes cancer, for no one can contradict him, and in all probability he will find acquaintances to furnish him with "facts" in corroboration of this view. The next question put is whether tobacco "is all that it has not yet been declared to be?" and I pause before its exhaustive character. Most of the tobacco that has been analysed has been pure; but some of it has been associated with very [illegible] put any limit to the [illegible] asked whether wool [illegible] kin; and the answer depends mainly upon climatic and other conditions. Under some of these conditions either silk or cotton is to be preferred; when wool, in other conditions the best, may be the *worst of the materials commonly employed for* un[illegible] clothing. The next question is, "Does ozone [illegible] pulmonary disease?" Yes, certainly, if inhaled ir [illegible] great a degree of concentration; although, as u [illegible] present in the atmosphere, it is as harmless as the *alcohol in hot-cross buns. An inquiry* whether bread-and-milk is explosive arrests one for want of definitions. Bread may be or may contain anything if the legal penalties are disregarded; and milk has more than once been responsible for explosions of epidemic disease. It is asked next whether the daily newspaper is a source of contagious and infectious disease, and whether we ought only to read it in gloves and a respirator? No doubt the newspaper falls within the general class of fomites to which the physicians of the last century paid so much attention; and a cleanly person who entered a public library in a slum district might be thankful for gloves, even if he dispensed with the respirator. Then it is asked whether it is as beneficial to [illegible]

[illegible] this question was examined by the late Dr. W. B. Carpenter many years ago, when vegetarianism was a comparatively new idea and when its supporters claimed for themselves a special endowment of the virtues arising from a complete control of all animal passions. He showed that the extremes of ferocity and gallantry were to be found *among vegetable feeders; and he instanced* the rhinoceros and the cock as familiar examples of the facts. It may be [illegible] ole opera notion of the soldier [illegible] atory disposition, the amenity [illegible] of the "military spirit." Of this endowment there is no particular evidence among the ranks of vegetarianism more than among those of any other class.

I think that the questions put by "Paterfamilias" in the columns of *Punch* are more reasonable than many which are set by examiners for professional degrees and diplomas.

I am, Sir, yours faithfully,

April 17th. F.R.C.S.

THE DRAINAGE OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

WHOLESALE CONTAMINATION OF THE SUBSOIL.—APPREHENSIONS IN REGARD TO THE DRAINAGE SCHEME.—UNFAVOURABLE SITUATION OF THE EUROPEAN QUARTER.—THE NEED OF BUILDING REGULATIONS.

Cairo.

NEXT to the question of the water-supply comes that of the drainage of Cairo. As already explained,[1] the water-supply problem stands foremost because it is a question of the present. Everybody recognises the position; it is impossible not to see that the water is sometimes full of dark coloured matter, that it stains the linen, is hard, spoils boilers and engines, in fact, that it is unsuitable for domestic and industrial purposes. The urgency of the water question is therefore obvious to all. The drainage question, however, is little less urgent.

For a quarter of a century there has been talk at Cairo of drainage schemes and nothing has resulted; therefore, it is a little difficult to realise that now at last sewers are actually going to be constructed. As the result of these numerous disappointments a widespread lack of faith still prevails. It must also be borne in mind that the vast majority of the inhabitants of Cairo have no experience whatsoever of drainage schemes and do not know what they mean. They have never been taught the benefits that result from well-conceived and properly applied systems of drainage. *They do not realise that such measures have been the means* of saving millions of human lives and of prolonging the lives of other millions. But they do know that when the subsoil of Cairo is disturbed, when excavations were made for the foundations of the new premises of, for instance, the National Bank, and for *other large buildings, there were* cases of typhoid fever in the immediate neighbourhood. Thus it happens that to-day when it is proposed to lay sewers in all the streets this prospect has created something approaching a panic. The sense of the proportion of [illegible] and many persons inquire whether the [illegible] or the sewers will create an epidemic. [illegible] possible that, in spite of the somewhat [illegible] it is proposed to take, some cases of sickness may result from the moving of foul earth. With regard, however, to an epidemic the question presents itself the other way round. It is not a matter of creating an epidemic but, on the contrary, of getting rid of the epidemics that already exist, which are so firmly established that the conditions may more accurately be called endemic. The present death-rate at Cairo is scandalous. If the statistics of some typical European town that has a proper drainage system and water-supply be taken as an example, it will be found that even when, during the course of the year, there has been an epidemic, still the mortality of such a town will be much below the normal death-rate of Cairo When the streets are dug up to lay the sewers in Cairo there may be a good many cases of disease provoked by unwholesome effluvia. It is, however, quite certain that many cases of disease connected with insanitation exist already and will continue to exist in the future whether the new trenches are dug or not. According to the last official returns published during the year 1907 there were 342 deaths from diphtheria and 141 from typhoid fever, therefore it was not necessary to open up the streets to produce these diseases. The general death-rate among the Egyptians in 1907 was 38·4 and 27·4 among the foreigners. It is not till the drainage system is completed and a well-considered general programme of sanitary reform strictly applied that this devastating death-rate will be largely reduced and a real improvement obtained.

---

[1] THE LANCET, April 3rd, 1909, p. 1014.

The question in the public mind is whether, when the trenches have been dug and the sewers laid, there will be a reduction in the prevalence of preventable diseases. The scientific man can make only one answer. In the light of past experience, and going back to the time when it was not known how to build sewers properly, and when all sorts of blunders were committed, actually creating epidemics and resulting in the loss of many lives, the advantages of sewerage schemes are known to have far out-balanced the disadvantages; the sacrifice of life has been literally nothing in comparison to the salvation of life. It is impossible to have an omelette without breaking eggs, and Cairo cannot be purified without stirring up some filth. But it is better to stir up this filth and to remove it than to allow it, as at present, to continue to accumulate in volume and in foulness. As it is, Cairo has been described as a town floating on cesspools, and it was perhaps inevitable that it should continue to wallow in filth while the country remained in financial difficulties. Now, however, that Egyptian finances have been put in order we are promised that some money at least will be forthcoming to save the lives of the inhabitants. It is the duty of all sanitarians to see that the promises are carried out.

One of the leading sanitary reformers of France, the late Professor Brouardel, speaking of Toulon, described this great military port as a town built on *un sol féealien*. This definition can as appropriately be affixed to Cairo. In the first instance the natives had perhaps a better sanitary instinct. The custom that still prevails in rural districts is for the males to relieve themselves on the manure heap which is generally near the entrance of their dwellings; the females, desiring greater privacy, utilise for this purpose the roofs of their houses. In both cases nature's disinfectants, the air and the light, play upon and purify more or less that which is impure. But, and though this primitive procedure still prevails to some extent even in Cairo, its continuance has not been found practicable at least in the narrow and crowded streets. Consequently, cesspits were dug, but as it costs money and trouble to empty them they are deliberately made as porous as possible and the whole percolates into the surrounding subsoil. Thus the ground on which Cairo stands is impregnated throughout with fæcal matter and urine, together with all other sorts of foul slop water and organic substances in a state of decomposition. The purifying action of the earth is obviously overtaxed in such a densely populated centre as Cairo. The emanations from so foul a subsoil are well calculated to predispose the inhabitants to epidemic and other diseases. In the meanwhile, and till the drainage works are carried out, the only advice that can be given to persons who live in Cairo is that they should sleep in the top of their houses—that is to say, as far as possible from a soil which must be largely polluted.

Some owners of private houses and of large hotels have sought to cope with this evil by building various forms of cesspools based more or less on the septic tank principle. The manager of one fashionable hotel explained with justifiable self-congratulation how his cesspool acted so well that the effluent was quite clear, and such enterprise and public spirit deserve warm commendation. If everyone did the same the soil would not be so foul, for such a clarified overflow can be dealt with by the subsoil as the crude sewage cannot be. Besides, if a few houses and hotels do deal satisfactorily with their sewage, sewage from the rest of the town passes through the European quarter as it follows the natural flow of the subsoil water from the more elevated, more crowded, and filthy native quarters finally to reach the Nile. The natives with a true hygienic instinct have always avoided living on the banks of the Nile. They fear the floods, for if the water of the rising Nile does not actually penetrate into their houses it certainly comes up in the subsoil to within a few feet of the surface. Thus there is more damp, more miasma, and insecurity in regard to the solidity of buildings. Formerly what is now the European quarter consisted of spacious, umbrageous gardens, with but few low-roofed dwellings. To-day, and without any sort of regulation or restraint, speculators are constructing huge, lofty tenement houses dominating streets which are not wide enough in proportion to the height of the buildings. Thus they shut out the purifying light and air from above, while the atmosphere within these hot and lofty dwellings reeks of the effluvia from the soil below. It seems to all who consider the matter that by-laws regulating building operations should now be insisted upon.

Here is an experience. In a narrow yard between two big blocks of buildings I was shown the flagstones in which were the openings of vast cesspools into which both these blocks drained. At times the cesspools overflowed into the yard and the stains on the walls showed how high this concentrated sewage might reach. The inhabitants had the cesspools emptied, but this was of no use. In a few days they were full again, not with soil from the adjoining blocks but with infiltrations from the surrounding land, and when the Nile rises the cesspools overflow into the yard. The rise and fall of the Nile in the subsoil is one of the principal factors governing the whole problem. A medical practitioner related to me that he had built himself a house and thought he would dig for water. He went down some 20 feet before he could find any water. A little later, however, the Nile began to rise, and then the water in his well came up to within five feet of the surface. It is claimed that this annual inflow and outflow of the Nile in the subsoil of the lower parts of Cairo is a great benefit, for it washes away the dirt. But, on the other hand, if it does carry away some of the foulness it also helps to spread it about broadcast. The flood penetrates the cesspools and carries their contents into the surrounding subsoil. A small portion may reach the Nile, but the greater part of the contents of the cesspools is likely to be deposited in the earth, polluting the subsoil to such an extent that the inhabitants of Cairo are afraid to dig it up. Thus are engendered those apprehensions in regard to the drainage scheme which I have already mentioned.

To allay such fears an official statement has been issued by the sanitary authority and circulated in the press. We are thus informed that the trenches in the wider streets will in no case exceed the depth of five metres and in the narrower streets three metres. As these trenches are shallow they can be made very narrow, therefore the amount of earth to be disturbed and dug up will be reduced to a minimum. The authorities claim that there will not be more excavation than what actually takes place when new hotels and large houses are built. Further, to reduce the risk and to push forward the work more rapidly, there will be overhead cableways to conduct the material as soon as it is excavated to the trenches which are ready to be filled up. Any surplus matter that cannot be thus and at once dealt with will be covered with a disinfectant and carried away. What perhaps is more important, so far as the visitors are concerned, is the fact that none of this work will be done during the tourist season, for that season corresponds with the high Nile, when the water in the subsoil would interfere with such excavations.

The first object of course will be to prevent the further contamination of the subsoil by providing water-tight drains, and we may be sure that the work will throughout be as good as trouble and experience can make it. If Cairo has suffered long it at least enjoys to-day the advantage that during all this time other towns have made great experiments, have spent large sums, and have thus accumulated evidence affording many valuable object lessons for more backward localities. These indications as to what to do and what to avoid, now that the capital of Egypt is entering upon a career of sanitary reform, should prove of great practical service to its administrators and governors. From what I have seen of the drainage scheme it seems clear that considerable attention has been bestowed upon all schemes elsewhere existent. Many of these have been rejected as antiquated or as unsuitable, and much that is altogether novel is, I understand, to be introduced. Thus the plan before us is doubly interesting: first, because it proposes to render Cairo a healthy city though at present it is exceptionally unhealthy; and, secondly, because this is to be done by the application of the most modern procedures.

(*To be continued.*)

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol University.

THAT the establishment of a modern university is no light task is attested by a recent report of organisations founded at the beginning of the year by the lecturers of University College, Bristol. Each of these is controlled and promoted by an organising secretary with a "nucleus" committee to be increased at discretion. The first scheme is the establishment of a unit of the Officers Training Corps. This at present hangs fire, for although there are 45 students willing to join (the necessary minimum being 30) there is uncertainty as to whether the War Office can recognise the unit before the University charter is granted. The formation of a hostel for men students is also being promoted; data have been collected which show that specially erected premises would cost too much, so that buildings already standing will have to be adapted to the purpose. Similar considerations have determined the formation of a club for men students which is now in existence. It was found that a new building would be far too expensive, so negotiations were opened with a neighbouring restaurant proprietor, with the result that on March 2nd part of his premises were declared opened as a Students' Club. Members of the University College Union are to pay 10*s.* 6*d.* per session and non-members 21*s.* For these fees the members of the club (who already number 50) will have meals at special terms, the use of a reading-room, a billiard-room, and a cloak-room, with attendance. It is proposed to have evening lectures, and it is hoped that the union committee and the proposed debating society may meet there. The Birmingham University Club has spontaneously offered to make arrangements for reciprocity of membership. The fourth organisation, an Association of Alumni, was referred to in my last letter. The committee appointed to organise athletics hopes to arrange annual matches in football, cricket, and tennis with the University of Birmingham and also between the various departments of the University.

University College: Department of Economic Biology.

In the course of an interim report to the Senate and Council of University College, Bristol, the executive committee of the Department of Economic Biology (which has been in existence [illegible] the work done. T[illegible] field trials, consu[illegible] Under the heading of research mention is made of investigations relating to fowl tuberculosis, the development and maturity of local crustacea, the geology and chemistry of the soil of cider orchards, the application of electricity to plant growth, a root disease of gooseberry and black currant bushes, a disease of mangolds, the yeasts of cider, and so on. The field trials have related to the use of calcium cyanamide as a manure, the manuring of grass land, and the inoculation of leguminous crops. The department has been consulted many times with regard to insect pests, poultry breeding, and [illegible] of these have been exhibited by request at agricultural shows. A series of lectures on fruit growing and cider making, and others on anthrax and actinomycosis, have been fairly attended. A brief account of investigations into the scientific aspects of Cheddar cheese making is given by Mr. D. Spence, Ph.D., who was appointed to this work by the department, the expenses being paid by the Somerset county council. He finds that pure cultures of bacteria may be used with advantage as "starters" in cheese making, and attributes the colouring of cheese, in part at any rate, to the action of enzymes. Other important observations have been made on the salting and fat content of cheese. The report is of great interest in that it shows how well agriculture may in the future be served by scientific research.

Bristol Eye Dispensary.

The ninety-seventh annual meeting of the supporters of this institution was held on April 6th. The report stated that the number of patients attending in 1908 had been 2408, an increase of 53 over the preceding year. The total receipts were £207 and the total expenditure was £217. An increase in the number of regular subscribers was asked for. The examination of school children has meant an appreciable increase in the number of refraction cases, and there was a general feeling at the meeting that the education authorities should not allow this work to fall upon a charitable institution. In the evening the dispensary staff exhibited a number of interesting cases to medical men who were invited. There was a good muster and this was felt to be a successful innovation.

The Barnstaple Rural District and the Local Government Board.

As already stated in THE LANCET, the Local Government Board considers that it is impossible for one sanitary inspector to be responsible for the Barnstaple rural district, and consequently insists on the appointment of an additional officer. The Barnstaple rural district council has again urged the Local Government Board to alter its decision, but the Board refused to do so, and in a communication read at the meeting of the district council held on April 16th again informed the council that an additional sanitary inspector must be appointed. A resolution was passed, which will be sent to the Local Government Board, stating that the district council will still continue its present arrangements. This means that the council will have to pay the whole of the salary of the sanitary inspector, as previously the Local Government Board had allowed half of the amount.

The Gloucestershire County Council and Post-mortem Examinations.

At a meeting of the Gloucestershire county council, held on April 15th, the chairman stated that the finance committee had written to the Home Secretary in consequence of the number of post mortem examinations ordered by the coroner for the southern division of the county, Mr. E. M. Grace. The Home Secretary having informed the committee that the matter was not in his jurisdiction, the Lord Chancellor had also been approached upon the matter and he had acknowledged the receipt of the letter, and although the committee had again written to him it had received no acknowledgment of its communication. As the chairman remarked there was no other person to whom to refer the matter, it is presumed that the subject will now drop.

Alcoholism and Medicated Wines.

At a meeting of the sanitary committee of the Cornwall county council held on April 15th Mr. J. M. Nicholls, J.P., of St. Ives drew attention to the question of medicated wines. He stated that as a medical practitioner it had come to his knowledge that temperance people were recommended medicated wines and had thought them a "wonderful pick-me-up." Mr. Nicholls proposed that it should be pointed out to the Board of Trade that it was desirable that all medicated wines should show in a prominent part of the label the percentage of alcohol and nutrition which they contained. The committee decided to adopt Mr. Nicholls's suggestion.

The Exeter Asylum.

At a meeting of the Exeter city council held on April 7th it was decided to obtain the approval of the Commissioners in Lunacy for the proposed extension of the asylum and the erection of a residence for the medical superintendent. The cost of the scheme is estimated at about £10,000, and it was determined to apply to the Local Government Board for permission to borrow that sum.

Death of John Careful Mackay, M.D. St. And., L.R.C.P., L.R.C.S., L.M. Edin., J.P.

Dr. J. C. Mackay, who died at Melness, St. Columb, Cornwall, on April 7th, in his fifty-seventh year, was born in Watten, Caithness, and qualified L.R.C.P., L.R.C.S. of Edinburgh in 1877. He commenced practice at St. Columb in 1882 and was shortly afterwards appointed medical officer of health of the district. For several years Dr. Mackay was medical officer of the workhouse and public vaccinator of the third, sixth, and seventh districts of the St. Columb union. He also for some considerable time held a commission in the 2nd V.B Duke of Cornwall's Light Infantry, retiring with the rank of Surgeon-Captain. In 1893 he graduated M.D. of St. Andrews, and in 1908 he was placed on the commission of the peace for the county of Cornwall. On his retirement from practice after more than a quarter of a century's professional work in St. Columb and the district, his many friends and patients presented him with a solid silver tray and tea service and silver rose bowl, accompanied by an illuminated address with 381 signatures of subscribers. Dr. Mackay was a staunch Churchman and a generous contributor to the restoration of the fine old parish church of St. Columb which took place about four years ago. He will be much missed at St. Columb, where he was highly respected, for he always had taken a great interest in all movements calculated to promote the welfare and pleasure of the inhabitants. His aged mother survives him and sincere sympathy is felt with her and his widow. The funeral, which took place at St. Columb Cemetery on April 10th, was largely attended.

pril 20th.

BIRMINGHAM.

(From our own Correspondent.)

The University.

The summer term commenced on Monday last and, recognising the shortness of the period which now separates them from the examinations, the students have thrown themselves quickly and heartily into their work. The number of new entries cannot yet be estimated, but the prospects appear favourable, though it is not usual for many students to enter in this term. It is rumoured that some important changes will take place in association with the surgical staff of the University before the winter term commences, but no official statements have yet been made with regard to the matter.

The Children's Hospital.

At the last quarterly meeting of the board of governors of the Children's Hospital, a deputation from the Aston Villa Football Club and the Variety Theatre's Charity Sports Committee presented to the hospital a cheque for £1000 for the purpose of endowing a new cot. In making the presentation, Mr. F. W. Rinder, who represented the football club, stated that the Aston Villa club, since its formation, had been the means of raising and distributing for charitable purposes over £25,000, and he assured the governors that the sports committee would give what help it could to the scheme for the new building. Speaking for the sports committee, Mr. J. E. Margoschis said that in addition to subscribing to many other charities, and beyond the sum now presented to the Children's Hospital, his committee had, since its foundation, handed over to the General, the Queen's, and the Children's Hospitals a further sum of about £1500, and he hoped that the work would be continued for many years.

The Health of the City.

Dr. J. Robertson's report for the week ending April 17th is the most satisfactory report which he has issued this year, for although the total death-rate—18·4 per 1000—is 1·4 per 1000 higher than that recorded for the week-ending April 3rd, the other features of the report are all very satisfactory. In the first place, the city is free from typhoid fever; there have been no deaths from this disease during the past fortnight. No fresh cases have developed and the hospital is empty. The other satisfactory features recorded in the report are the decline of the epidemic of measles and the decrease of diphtheria. In the week ending April 2nd there were 30 deaths from measles, but last week only 11 deaths were due to that cause. As regards diphtheria, the number of cases in hospital has been reduced from 107 during the week ending March 6th last to 64 last week, and the total zymotic death-rate has fallen to 2·6.

The Water-supply and Lead Pipes.

It has been repeatedly stated that our Welsh water-supply is dangerous on account of the solvent action of the very soft water on lead pipes; the statements have never been supported by any satisfactory proofs, and as the result of a series of experiments made by the city analyst they may be dismissed as devoid of foundation. Samples taken at intervals from consumers' taps were found devoid of any serious amount of lead. If the water is allowed to stand in lead pipes for a month or more it does dissolve a certain, but not an excessive, amount of lead. The experiments showed that water standing in lead pipes exercised some influence in making a protective covering, and taken as a whole the results of the experiments indicate that the Welsh water has no violent action on lead pipes, even when the pipes are new, and what action there is rapidly decreases as the pipes become older.

The Adulteration of Butter and Milk.

The annual report of the city analyst for the year 1908 shows that so far as butter is concerned there was less adulteration by preservatives than in any previous year; on the other hand, the amount of adulteration in other ways showed an increase over 1907, but was less than in 1906. The adulteration of milk by preservatives was also very slight, but the proportion of adulteration by water or skimming was greater than in the four preceding years. The latter result, however, in the opinion of Mr. Liverseege, does not actually indicate an increase of adulteration, but is due to the increase in the number of samples taken. We may, therefore, congratulate ourselves that, so far as adulteration of two of our principal foods is concerned, there appears to be less adulteration than in the past, and as the prosecutions of the adulterators have resulted in many cases in the infliction of severe fines we may hope to suffer still less from adulteration in the future.

Medical Inspection at Smethwick.

The first annual report of Mr. W. F. Marsh Jackson based upon the examination of 6897 children in Smethwick schools is decidedly optimistic, as may be gathered from the reporter's conclusion that the results he has obtained justify the opinion that so far as Smethwick is concerned there is no manifestation of physical degeneration. Nevertheless, it appears from the report that nutrition was below the normal in 23·8 per cent. of the cases, that the teeth were defective in 22·4 per cent., and vision in 15·2 per cent. The defects of hearing were less numerous; there was only a small proportion of lung and heart diseases; and a still smaller proportion of tuberculous affections.

April 20th.

LIVERPOOL.

(From our own Correspondent.)

The Report on the Liverpool School of Tropical Medicine.

The Government Blue-book containing the annual report of the Advisory Committee for the Tropical Diseases Fund for the year 1908 has recently been issued. From this Fund the Liverpool school receives a grant of £1000 per annum The report speaks highly of the accomplishments of the school, the committee stating that it is of opinion that the work continues to be of a high order of merit and fully justifies the continuance of the grant. The Government grant is spent partly in payment of the salaries of special lecturers and partly towards the cost of research work carried out at the school. The committee approves of the work to be carried out by means of this grant. It is satisfactory to find that the work of this school continues to merit expert approval, as all who know anything of public events felt confident that it would. There is no department that has done more to increase the reputation of the University of Liverpool than the School of Tropical Medicine. It is known all over the world, and its great work in the cause of humanity is everywhere appreciated. Professor Sir Rubert Boyce, who was sent by the Liverpool School of Tropical Medicine, at the request of the Secretary of State for the Colonies, to Barbados to investigate a slight outbreak of yellow fever there, has now left Barbados on a tour round the neighbouring West Indian Islands with a view to advising on matters of sanitation. Sir Rubert Boyce completed a great amount of work whilst in Barbados and, in addition, delivered useful lectures on sanitary science to the medical staff of the island, the leading merchants, the agricultural societies, and the consular corps, having been in touch with all classes of the community, and directed a very straightforward message to all. Dr. A. Kinghorn and Mr. Montgomery, who were sent out to Central Africa on behalf of the Liverpool School of Tropical Medicine to inquire into the possibility of, and means of, checking the spread of sleeping sickness into British Central Africa, have recently returned to England after a sojourn of about two years in those territories.

The Proposed New Out-patient Department at the Royal Southern Hospital.

The new out-patient department at the Royal Southern Hospital will occupy a site in Caryl-street immediately opposite the main building. The land was acquired and cleared by the committee some years ago in anticipation of the necessary funds for building which, I understand, are now forthcoming. The cost of this much-needed provision for the proper dealing with some 50,000 attendances of out-patients a year will be about £8500, of which the city council is empowered to vote £4000. The whole of the amount is now available, but for furnishing the new department there is still required an additional sum of £1200. In the erection of the new buildings the latest scientific ideas are being carried out. In order that the out-patients may not communicate infection to the in-patients, the new building is to be completely separated from the hospital proper; and, in the second place, the plot of land is large enough, being 960 square yards in extent, to allow the air to circulate freely all round. The large waiting-hall, which is to be placed in the middle of the building, will be carried considerably higher than the surrounding offices, thus enabling the whole to be lighted on all four sides, and the windows will be arranged so as to afford a thorough draught. Suitable accommodation will be provided for the medical and nursing staffs, separate entrances being provided. The building is to be faced with red pressed bricks and stone bands, and the roofs are to be slated with the outputs of British quarries. Building operations will commence immediately, and, when completed in about 12 months' time, will result in an ornate building which will be an important addition to the hospital equipment of the city.

The Fireguard Clause of the Children Act: The First Liverpool Prosecution.

The first Liverpool prosecution under the "fireguard" clause of the Children Act was heard at the Dale-street police court on April 16th. The defendant, a widow, was charged with having allowed her daughter, aged six years, to be in a room where there was a fire in an open grate without [illegible] the child being burnt. [illegible] working at the time [illegible]eaded poverty as the reason for not being able to provide a guard. The magistrates advised the woman to procure one and dismissed the case, as the police confirmed her protestation of poverty.

Death of Edward Penrose Twyford, M.D. Edin.

Dr. E. P. Twyford, late of St. Helens, died on April 8th, at his residence at Birkdale, near Southport, as the result of a short attack of pneumonia. The deceased retired from practice a few years ago after 55 years of active work. The death of his only daughter, Mrs. Gray, widow of the late Dr. Gray of St. Helens, at the beginning of this month, had a very depressing effect upon him, and probably accelerated his death. He was 78 years of age. He held the commission of the peace for the borough of St. Helens and also for the county of Lancaster, and was held in the highest esteem by the inhabitants of St. Helens and neighbourhood.

April 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Aspects of the Poor-law Commission Report.

CERTAIN points of notable interest and importance were brought to the front the other day in a discussion before the Economic Section of the Royal Philosophical Society of Glasgow on Some of the Medical Aspects of the Poor-law Commission Report. Dr. John C. McVail, medical officer of health of Stirlingshire and Dumbartonshire, in opening the discussion put forward a scheme with the idea of checking disease, not only in paupers, but at its very beginning also in those who were not paupers, but through illness had every chance of becoming so. It was suggested that this should be done by medical provident institutions. If the country were divided into areas for medical provident purposes, if all the medical men living within that area were allowed to put their names on the list of the institution as willing to act, if all who were willing to receive its benefits were allowed to contribute a fairly sufficient amount to make them realise that what they were getting was worth paying for, the State might subsidise such institutions so as to have a share in the control. In institutions of that kind there was no reason why there should not be periodic visits by the medical man to all the cases on his own list, not very frequent, say once in the 12 months. He would visit, not because he had been sent for, but he would go to the homes to see whether the people were well, to ask questions, to give guidance to parents as to the upbringing of children and the kind of occupation for which they were fitted. All that might be Utopian, but Dr. McVail could not see why some such scheme should not be adopted. In the course of subsequent discussion Dr. A. K. Chalmers, medical officer of health of Glasgow, referred to the question of charitable medical relief in Glasgow, stating that he had worked out for another purpose there were 140,000 people receiving such aid every year, or one out of every five or six persons.

Convention of Royal Burghs of Scotland.

At the convention held in Glasgow recently the Lord Provost of Dundee called attention to the subject of pulmonary phthisis and the position thereanent of the public health authorities, and moved that the matter be remitted for further consideration. It was also suggested that the Government be asked to give a grant to local authorities, who either by themselves or in combination would take active steps in dealing with the disease. It was pointed out, on the other hand, that if in Glasgow they treated pulmonary tuberculosis as they did scarlet fever and other ordinary infectious diseases they would have 3000 consumptive cases for hospital and 1*s.* per £ would not cover the cost. The Glasgow health committee was spending its energy in seeking to get at slum property and insanitary workshops, and in that way preventing people from contracting the disease.

Medical Inspection of Dumbarton Schools.

The Scottish Education Department has recently issued a memorandum on the subject of medical inspection of schools, and has advised boards to hold their hand until information has been obtained for the Department and workable schemes formulated. Notwithstanding this the School Board of Dumbarton has decided to have a preliminary medical inspection of the children in the burgh schools made by the local medical men with the view of assisting the board in determining (1) whether the condition of the children requires that the board should submit a scheme for the approval of the Department, and (2) what scheme, if any, should be submitted. The Departmental memorandum lays it down that any expense incurred by boards in this connexion will not be sanctioned till schemes have been adopted, but that difficulty is being overcome in Dumbarton by the medical men volunteering to carry out the preliminary inspection in question free of charge. It is computed that this action on their part saves the board a sum of £200.

April 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Vivisection in the Lay Press of Ireland.

ONE of the gratifying signs of the times recently made manifest in Ireland is the very active sympathy with scientific research which has of late been obvious in all directions. A specially encouraging example was a leading article which appeared on April 19th in the *Freeman's Journal*, in which sympathetic attention is called to the fact that "the people of science have been forced to start a Research Defence Society to meet the attacks of the sentimentalist." The testimony contained in the recently issued volume of the society our contemporary finds to rebut "the charges made violently against honest and humane men who work in the laboratories seeking the cure of human diseases and find in animal reactions the test of many medicines and in the examination of animal organisms the secret of many living processes and of many maladies and remedies." The writer proceeds to point out that the undeservedly abused votary of physiological and pathological science and the truly benevolent worker in the best interests of humanity, "plead not guilty to the charge of inflicting pain upon animals, and they are very proud of having conferred great good upon humanity." The testimony of Professor E. H. Starling is quoted with thorough appreciation, to the effect that though he has been for 17 years engaged in the experimental pursuit of physiology yet he can say that "on no occasion has he ever seen pain inflicted on a dog or cat in a physiological laboratory in this country." In presence of the conditions and environments which influence the embryonic growth of our new Irish University, such candid and discriminating expression of lay opinion may be looked upon as one of the most encouraging omens of our national scientific progress.

Hospice for the Dying, Harold's Cross, Dublin.

All critical observers, friendly or otherwise, admit that the number and efficiency of the medical charities of our Irish metropolis stand relatively high among those of the various other capital cities of civilised nations. And the Hospice for the Dying, Harold's Cross, Dublin, is a unique institution even for Dublin. The claims of this institution were eloquently pleaded on Sunday last by the Very Rev. T. Maher, S.J., who detailed the circumstances under which this institution was founded a quarter of a century ago. The fact is recognised by all visitors that those victims of fatal disease who seek the refuge of the hospice are treated during the closing days of their lives with watchful care; and all Father Maher's hearers fully realised what a high standard of attainment the institution represented, having regard to the work which the Sisters of Charity are continuously engaged in performing in so many other fields of charitable endeavour. A large proportion of those who seek the shelter of the hospice are either poor patients who have been discharged from the general hospitals as incurable cases, or destitute ones who have been discovered in miserable and uncared-for surroundings by the sisters in their visits among the very poor. The consoling advantages to the destitute dying of the change to surroundings in which every possible attention and comfort are supplied cannot be over-stated. Since the foundation of the hospice thousands of victims of hopeless disease of all ages and of every creed have been sheltered and cared for within its walls, and every philanthropic citizen of Dublin, and of Ireland at large, feels hopeful that the generosity of our people will enable it to continue its splendid work.

Action by a Nursing Home.

The Irvinestown board of guardians were sued by the Belfast Incorporated Nurses' Home on April 17th at Enniskillen, before his honour Judge Craig, county court judge, for £2 18*s.* 4*d.*, in the following circumstances. It appeared that a nurse from the Belfast Nurses' Home was absent on sick leave at the Irvinestown Workhouse Hospital from Nov. 18th, 1908, until Dec. 2nd, 1908, but that during that time her sister, who is also a nurse connected with the Belfast Home, performed her duties and took her place. The guardians refused to pay the original nurse's sister for her services on the ground that they only allowed the sick leave on the understanding that she was to pay her own substitute. His honour, in giving a decree for the amount claimed, said in his opinion it was a shabby thing for the guardians to defend the action at all.

Mortality in Ireland.

For the week ending April 10th the highest death-rate in Ireland was recorded in Newtownards—viz., 40 per 1000 per annum of the population of the district; Ballymena, county Antrim, has a rate of 35·5 per 1000; and Galway, one of 35 per 1000. No other town exceeds 30 per 1000. The lowest rates were in Tralee (county Kerry), 5·3 per 1000, and Waterford, 9·75 per 1000. No other town was below 10 per 1000. The rate in Belfast was 27·0 and in Dublin 25·5 per 1000. The average rate in Ireland was 24·5 per 1000. The deaths from zymotic disease were 1·5 per 1000. 16 of the town districts had no deaths from zymotic diseases. Ballymena had three deaths from measles and one from diphtheria, and that town had the highest zymotic death-rate—19 per 1000.

The Irish Universities Commissions.

The two commissions appointed to draw up statutes, &c., in regard to the National University and the Belfast University, are working hard so that if possible both new universities may be able to begin work next October, when, if they are both ready, the Royal University will be dissolved. The National University Commission has made considerable progress in the financial arrangements, while the Belfast body has in the past given more attention to the framing of the statutes which are now practically complete. The National University Commission will have, it is said, special professorships in various branches of Celtic, and it is announced that the Belfast Commissioners propose to make appointments to the following additional professorships: modern history, economics, French and Romance philology, and botany. They also propose to make appointments to the following additional lectureships or readerships: archæology and ancient history, English language, Celtic languages and literature, logic and scholastic philosophy, physics, geology, organic chemistry, and bio-chemistry.

April 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Outbreaks of Typhoid Fever among Soldiers.

AT a meeting of the French Society of Military Medicine held on April 1st M. Rudler gave an account of an epidemic of typhoid fever which was attributed to infection of clothing and hands incurred by the men during a bathing parade for horses. M. Collignon then gave an account of the outbreak of typhoid fever which lasted for some 20 years—that is to say, between 1888 and 1908—in the 25th Regiment of Infantry stationed at Cherbourg. The outbreak was evidently due to the water of the Divette which was fouled by surface drainage. Despite the installation of Chamberland filters and afterwards of sterilisers on the Salvator principle, the fever did not disappear from the regiment until the day when the only drinking water used was boiled and flavoured with tea. On two occasions this supply was interrupted and the fever reappeared. This was due to the fact that there were two supplies of water, one being sterilised and the other impure, and the men, despite all precautions and the severest penalties, would go on drinking the impure water, which to their eyes appeared exactly the same as the sterilised water. M. Collignon proposed that in all garrisons where the water-supply was suspected the drinking water which was distributed should be boiled, flavoured, and sweetened. Another epidemic of typhoid fever broke out recently at Vannes and M. Collin gave an account of its origin. There are stationed at Vannes two regiments of artillery and two companies of infantry. One only of these two companies was attacked, while all other members of the garrison were immune. The company which was attacked used to eat salads which were supplied to them by a market gardener. This man had a daughter who was suffering from typhoid and her excreta were thrown into a ditch which was in the garden and also sometimes on the vegetable beds. Besides, there was a well only a few metres below this ditch and the water of this well was used for watering the garden. A bacteriological analysis revealed the presence of the coli bacillus upon the salad vegetables. 44 soldiers were attacked and five died.

Radium in the Treatment of Malignant Disease of the Œsophagus.

At a meeting of the Hospitals Medical Society held on April 2nd M. Guisez and M. Barcat said that in patients who were suffering from cancerous stricture of the œsophagus, which had been diagnosed both by œsophagoscopy and by examination of a fragment of the growth which had been removed, they made a careful examination to assure themselves that the passage of the œsophagus was free and then introduced a sound armed with radium bromide, which they left in place for several sittings of four to five hours. In these cases they used the highly penetrative rays of Dominici. The result of this treatment was the complete disappearance of the foul and blood-stained secretion and an augmentation of the calibre of the œsophagus, which in two of the patients got back to almost its normal dimensions. The speakers considered that, even if there is no cure, this method of treatment considerably relieves the condition.

Collargol in Surgical Affections.

At a meeting of the Surgical Society of Paris held on April 2nd various members gave their opinion as to the employment of collargol in surgical affections. M. Reblaud gave it as his opinion that as a local antiseptic in urethro-vesical troubles collargol was very inferior to nitrate of silver, but in uterine infections following upon abortions and in septic pleuritic effusions when surgical intervention alone did not bring about a fall in temperature the association of collargol brought about rapid defervescence. M. Dupuy, in a case of very extensive injury of the rectum, obtained rapid cicatrisation by the use of gauze wicks impregnated with vaseline containing 10 per cent. of collargol.

Hot Air in Surgery.[1]

At the same meeting of the same society M. Bonamy and M. Muller said that since February, 1907, they had been in the habit of applying hot air in surgery at the Gouin Hospital. They had used the treatment in gangrene, both diabetic and traumatic, in ulcerating cancer of the breast, epithelioma of the neck of the uterus, and sundry skin diseases. They showed the patients and the Gaiffe apparatus which they had used. It seems fairly certain that this method is destined to play a considerable therapeutic rôle.

The Treatment of Laryngeal Stenosis by Gutta-percha Bougies.

At a meeting of the Academy of Medicine held on April 10th M. Sieur gave an account of two cases of laryngeal stenosis successfully treated in the following way. After a preliminary laryngostomy the larynx was dilated with gutta-percha bougies gradually increasing in size. The first case, due to the bite of a horse, was cured in 15 days. The second case, in which the stenosis followed an attack of enteric fever, had to be treated for a year but the result was quite successful.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Influence of Light upon Gelatin.

THE therapeutics of the curative and bactericidal properties of light would rest on a firmer foundation if we had more knowledge of the decomposition which the light rays provoke in the chief constituents of the living organism, particularly in the proteids and albuminoids. Great interest was therefore taken in a paper, read at a recent meeting of the Copenhagen Medical Society by Dr. Aage A. Meisling, on his original researches regarding the sensitivity to light of albuminoid substances. The most important results of his investigations on the action of light rays on gelatin were as follows. Pure gelatin is in itself, he found, sensitive to light, so that it is sufficient to expose it for five to ten minutes to a Bang electric arc lamp in order to obtain demonstrable alterations of the gelatin. This sensitivity to light increases very considerably when the gelatin is coloured by certain aniline dyes, for instance, erythrosine, eosine, or auramine, which dyes can be shown to act as catalytic agents. After exposure to light gelatin evidences the presence of formaldehyde. This production of formaldehyde from the gelatin is greatest after exposure to the blue, violet, or ultra-violet rays. The action of light on gelatin may be demonstrated and measured by either physical or chemical methods. To name an instance of the former method, those parts of a pure gelatin plaque that have been exposed to the action of light can be shown to acquire thereby a diminished faculty of water absorption, so that if after the exposure to light the plaque is placed in water prominences arise upon it, being formed at those parts of the plaque from which the light has been excluded. Similarly, very beautiful patterns in relief may be obtained by making the light act through an ordinary photographic negative on a gelatin plaque, sensitised by erythrosine, and afterwards placing the plaque in water. The gelatin acted upon by light will be found also to acquire an altered solubility in water, so that the parts which have not been subjected to light will alone dissolve when the plaque is placed in water, that is to say, the physical action of light on gelatin is a hardening one. One of the chemical changes which take place in illuminated pure gelatin is an oxidation, another the formation of formaldehyde, which has already been mentioned and which explains in a satisfactory way the hardening and coagulation just described. A further peculiar property of illuminated gelatin is its increased power of absorption of colouring matter. When, for instance, a gelatin plaque is placed in a solution of an aniline dye, the parts that have been exposed to light become far more strongly coloured than the rest of the plaque. In this way beautifully coloured copies may be obtained from photographic negatives. Under certain conditions the light produces not only formaldehyde but also hydrogen peroxide in the gelatin: this formation of hydrogen peroxide is due to the presence of sulphuric acid, resinous matter, and other substances, not to the pure gelatin itself. Both formaldehyde and hydrogen peroxide are oxidising agents, though acting in a different way; when acting together they bring about very strong oxidations of an extremely complex nature. With mixtures of formaldehyde and hydrogen [illegible] simply mixtures of the two mentioned chemical bodies. In summing up Dr. Meisling said that in his opinion the chief importance of his investigations might be found in the fact that some of the enigmatical "vital" processes particularly connected with the colloid substances had been shown to follow simple physical and chemical laws. Dr. Th. Madsen and Professor C. J. Salomonsen congratulated the speaker on his important work, which they said would undoubtedly give a new impulse to the chemistry of colloids.

The Vaccine Treatment of Staphylococcic Diseases.

At the same society Dr. Vilh. Jensen read a paper on his experience with the vaccine treatment on Sir Almroth Wright's principl[illegible] the treatment of [illegible] in the extreme, se[illegible] cured. He had also seen good results in some cases of acne vulgaris, in a case of staphylococcic sycosis barbae, and in a case of staphylococcic septicæmia. Two cases of actinomycosis failed to show any improvement, but in both cases the patient was in the last stage of the disease.

April 20th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Weather and the Visitors.

HARDLY more than a week ago we were wincing under a chill nor'-easter charged with indurated snowflakes—*nevischio*, in Italian parlance, or baby hail-stones—which never fell to the ground, but whirled through the air like the many-tailed whip of the flagellating Furies; and now we are revelling in sunshine just redeemed from sultriness by the zephyr blowing from "the *bijou* Bernese Oberland" rapidly fading from the Apennines. A longer, severer winter has never been followed more suddenly by so delicious a spring, and every interest, urban as well as rural, is enjoying the blessed change. Many a landlord of a hotel, who might have sat for the frontispiece of "Zimmermann on Solitude," has now to give up his own bedroom to the importunate guest, the latter being lucky if he has not to bivouac in the billiard-room or to find a dormitory in the recess of a bow-w[illegible] arrival, unless he has secured [illegible] met by the hall-porter "with h[illegible] in Rome the caravans of pilgrims, mainly from France, are only saved from camping out in the open by being billeted on private citizens or provided for in temporary holdings improvised in hot haste by the Vatican. Fortunate, indeed, will it be if the heavy sick-list or even death-rate of the last few "Siberian" months is not increased by promiscuous over-crowding in conditions too often suggestive of the "Black Hole of Calcutta"!

The Health of the Queen-Mother.

Disquieting rumours as to the Dowager Queen Margherita have for some time been in circulation, rumours gaining rather than losing in the process of transmission. The facts, I find on inquiry, to be these. Her Majesty is at present suffering from facial neuralgia supervening on influenza—

---

[1] THE LANCET, March 20th, 1909, p. 877.

neuralgia, moreover, somewhat irresponsive to treatment. The prognosis, however, is quite favourable and the general conditions of the august patient are satisfactorily maintained. The Queen-mother, I am further informed, improves in proportion as she consents to keep not merely to her room but also to bed, in accordance with the advice of Her Majesty's consultants, impressed as they have been with the draughts made on her strength by the anxieties and the exertion consequent on relief work on behalf of the survivors of the earthquake.

The Debate in the Senate on the Earthquake.

An animated, occasionally overheated, discussion on the Government's remissness in aiding the sufferers from the recent earthquake on the Siculo-Calabrian seaboard has just awakened unwonted echoes in the tranquil *ambiente* of the Upper Chamber. A Bill for "Opening an account between the Treasury and the Minister of Public Works to provide for the urgent wants of the communes visited by the telluric storm of Dec. 28th, 1908," evoked from the veteran surgeon, the Senator Francesco Durante, a series of trenchant criticisms on the delays and general inefficiency of the relief work hitherto attempted. A vivid sketch of the cataclysm and its immediate consequences preceded Dr. Durante's impeachment, in the course of which he dwelt on the fact that the wretched survivors of the visitation had to wander throughout all Italy, in island and on mainland, in quest of a hospitality made possible by the subventions of the outlying world. "Charity," continued the Senator, "however great, has its limits, and the *profughi* have now for some time been a prey to misery and privation, in not a few instances breaking out into turbulent protest and forming an element of local unrest and disorder. After three months Messina and Reggio and the townships in their respective provinces are precisely in the same conditions in which they were found on the morrow of the disaster. *Poco si è fatto e quel poco non bene* (little has been done and that little badly)!" He was especially severe on the construction of the *baracche* (huts). "They will not last more than one year, their material being of fir-wood and their site ill-chosen. Better would it have been, *pari passu* with the construction of well-found huts, to proceed actively with the clearing away of the débris of the collapsed quarters, under which there are still many tenements and shops capable of harbouring in comfort and in business no inconsiderable part of the population." A Messinese by birth, the Senator Durante spoke feelingly on a subject near his heart, and when His Excellency Signor Bertolini (Minister of Public Works) attempted to rebut, or at least to minimise, the doctor's criticisms, he was met by the retort that whereas he grounded his statements on the reports of officials themselves inculpated, the criticisms were inspired by experience gathered by impartial eye-witnesses on the spot. "There is also," continued Dr. Durante, "the problem of alimentation to be solved, and I ask, how is a population to live without occupation, industrial or commercial? First of all," he concluded, "clear away the débris, restore the conditions of life impossible in cities composed only of huts. Short of such rehabilitation Messina will never rise again." The veteran consultant's speech made a profound impression on the Upper House and (as reported) throughout the country, confirmed as it is in some important respects by the ocular evidence of visitors, including no less a witness than ex-President Roosevelt.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Medical Congress at Budapest.

ALTHOUGH the organising committee of the approaching International Medical Congress has not issued any information as to the effect upon the congress in case war should have broken out every Hungarian physician nevertheless has been in great anxiety about the success of the congress should the war really have disturbed it. At present Hungarian medical science is mostly in young hands, which would all have been needed in the battlefield. In Hungary there is compulsory medical service, and every able-bodied man is in the reserve service until his thirty-eighth or fortieth year. This is particularly binding upon medical men, of whom ten times as many as are available would scarcely be sufficient for service in the field. Should war have broken out the congress would have been deprived of half of its native supporters. Now that the situation is happily clear the preparatory committee is working with double diligence. Circulars have been sent t[illegible] societies asking them to send [illegible]. Town councils have also been asked to send one or two representatives from their medical boards and school physicians; in short, all medical men filling official positions are specially invited to the congress, which promises to be exceptionally well attended. I hope to be able to report the detailed programme of the congress in my next letter.

The Death of Professor Thanhoffer.

The Hungarian medical world is mourning the death of Louis Thanhoffer, the eminent anatomist. He was renowned for his achievements in the domains of pathological and physiological histology. The structure of nerve ganglions and the study of the nerve endings in different organs were the first objects of his study. When only 26 years of age he became professor of histology in the Budapest Veterinary College. He was transferred thence to the University as professor of anatomy and here he has worked incessantly with exceptional devotion. He was a man of great character and as remarkable for his scientific honesty as for his learning and talents. He often quoted as his motto, "*Qui proficit studiis sed deficit moribus, plus deficit quam proficit.*" He was the author of several excellent books, the best one being the "Comparative Physiology and Histology," which was crowned with the Balassa prize and which has been translated into the German and Russian languages. He was born in 1843 and died in his sixty-sixth year after a long and distressing illness. But a few months before his death he received from His Majesty the title of "Adviser to the Court" (Hofrat).

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Summer Term at the Medical Faculty of the University and some Figures for the Winter Term.

THE official announcement of the lectures and classes in medical subjects, to be held during the summer term 1909, in Vienna, has just appeared. The term lasts only three months, although it is called semester; it begins during the last week of April and the last lecture will be delivered on or about July 20th. Altogether 406 different classes and courses are announced, against 380 in the summer term, 1908. The number of professors engaged in this work amounts to 33 ordinary, 65 (as against 69 in 1908) extraordinary professors, and 149 (as against 134) *privat-docenten.* The number of ordinary students who attended the medical courses in the winter term, 1908–09, was 1660, amongst them 62 ladies and 385 foreign students, mostly English, American, and Russians. The increase over the previous winter term was about 5 per cent., but the percentage of students taking up medicine in comparison with the total number of students at the Vienna University has remained stationary during about four years; it is 22 per cent. of the grand total, showing that there is little, if any, percentual increase in the study of medicine, and the increase is due to the increase of population. As regards the lectures, some of the more important are as follows: Professor von Noorden on disturbances of metabolism, including gout and diabetes; Professor von Neusser on circulatory disturbances; Professor von Struempell on nervous diseases; Professor von Eiselsberg and Professor Hochenegg on general and special surgery; Professor Fuchs on ophthalmology; Professor Urbantschitsch on general otology; and Professor Chiari on laryngology. Special classes will also be held on otology by Alexander and Barany; on skin diseases by Nobl, Riehl, and Finger; on hæmatology by Schwarz and Türck; on pathology and morbid anatomy by Ghon, Stoerk, and Landsteiner; and sero-therapeutics by Paltauf and Kraus. As a rule, the fees for the courses are not high, £2 2*s.*–£4 4*s.*, according to the duration, mostly from 7 to 10 weeks. Of course, the above-mentioned classes are not the only ones announced.

A Laparotomy as an Object of Art.

Much comment has been raised by a picture, exhibited at present to the public at Vienna, which shows a noted Vienna surgeon at work, in the act of removing a myoma from the uterus of a middle-aged woman. The surgeon is Professor Wertheim, and his assistants are also well-known Vienna surgeons. The painter, Mr. Adams, an artist of considerable renown, has been mt [illegible] picture with its, from the [illegible] details. On the other han [illegible] attacked from different quarters for having given consent for exhibition, and has been accused of advertising, although he is above such a suspicion. The defenders of the novel idea of showing a serious operation to a public crowd contend that the famous picture "Anatomy," by Rembrandt, was inspired by the same idea, and that the renowned pictures of battles and shipwrecks are more gruesome and awe-inspiring than this aseptic, unbloody operation. But it must be conceded, even by an impartial surgeon, that the appearance of an incision in the abdomen, through which the contents, or part of them, of the abdomen are visible and protruding, does not belong to a very pleasing class of objects to look at. It is a matter of taste, and the fact that grave demur comes from artistic circles is a sufficient judgment on the matter.

Rupture of the Corpus Cavernosum Penis.

At a recent meeting of the Medical Society Dr. Paschkis showed a patient, aged 29 years, who came to him complaining of pain and swelling of the penis. The organ itself was found on examination to be m [illegible] ence at the base, the swelling [illegible] of blood. The patient had t [illegible] to turn the penis to the right [illegible] thing at the root of the organ give way, whereupon the swelling appeared and increased rapidly. There was marked tenderness, which, however, only existed along a small area of the left side, just at the base of the cavernous body, and a rupture of this body was diagnosed. An extensive hæmatoma, reaching high up over the pubes and down over the scrotal integument, was present. The only treatment adopted was rest and lead lotion applied every two hours. The swelling soon subsided, and now, six weeks after the incident, the patient shows a small indurated, somewhat tender, nodulated swelling of the base of the left corpus cavernosum. Erections are possible and slightly painful. As regards the etiology, it was contended that at the site of the rupture the condition of the tunica albuginea and of the blood-vessels must have been abnormal, otherwise this small injury could not have caused a tearing of this generally tough and resistant membrane.

April 14th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Unrest in Turkey.

THE mutiny of the soldiers which broke out in an unexpected manner on the night of April 13th, and which caused considerable bloodshed, seemed at first to corroborate the view of a large and earnest section of Europeans in Constantinople that the Turks are incapable of grasping their vital and essential responsibilities and of developing a constitutional *régime* on rational lines. Things seemed to be reverting to the old status of absolutism. Now, as I write, there is talk of civil war and talk of peaceful settlement, but the general opinion is that any settlement will be only temporary, and that in the near future new and fiercer conflicts will arise. In the meantime many of the military hospitals are filled with wounded and dying. The local newspapers say that about 60 people were killed, soldiers and civilians included, on the night of April 13th, but this is an under-estimate in order to pacify the excited minds of the population. What increases the anxiety is the uncertainty of the situation. Add to it the pernicious habit of the Greeks of unrestrainedly indulging in shooting at Easter time from all sorts of firearms, and it will be easy to form a fair judgment of the state of disquiet prevailing at present among all classes of the Ottoman metropolis. A good number of tourists have hastily left and some old inhabitants are thinking of following their example. Accidents of a grave and often fatal nature resulting from the indiscriminate use of revolvers by the Greek youth are quite common. The policemen seem to be helpless.

The Ottoman Pharmaceutical Association.

Over 200 pharmacists of Constantinople assembled lately in the premises of the Italian Società Operaia in order to deliberate on some important questions concerning the 35th Article of the Standing Regulations of the Ottoman Pharmaceutical Association. It was unanimously decided at this meeting that the delegates of the pharmaceutists should formulate and submit a new scheme of rules and precepts with regard to the actual status of the association, the rights and duties of its members, and the existing tariff, which is far from being satisfactory. In view also of the doubtful character of the Ottoman law which regulates, or rather ought to regulate, the practice of chemists and druggists, it was thought necessary to appoint a special delegation consisting of the president of the association, El Hadj Hamdi Bey, and Messrs. Irinéu and Husni Bey, to appeal to the authorities in order to bring about a more reasonable application of the law in question. This special delegation or commission will also take the necessary steps to guard the privileges of the association and to abolish the unlawful practices of numerous unscrupulous chemists and druggists, which practices are often prejudicial and even fatal to public health.

Transmitted Tubercle: An Extraordinary Cause of Lupus Vulgaris.[1]

Dr. Grossman, in an article which appeared in *La Pédiatrie en Turquie*, describes the case of a healthy boy, 13 years of age, who suffered from conjunctivitis and whose mother had perforated one lobe of his ear in order that he might be able to wear an ear-ring, which was a reputed charm against all disorders of the eye. The perforation was made with an ordinary needle. The woman, a neighbour, who assisted in performing the operation, made the needle wet with her saliva to facilitate its introduction. Soon afterwards the ear of the boy began to swell and in the course of time the wound degenerated into lupus vulgaris. Inquiries showed that the neighbour who helped the mother to perforate the ear lobe of the boy by wetting it with her saliva had died soon afterwards from tuberculosis of the lungs. The practice of wearing ear-rings as charms against the evil eye or disease is quite common in the Near East. As the needle used for that purpose is almost never properly cleansed and as no antiseptics are ever applied the result is very often infection of the worst type, as in the case now reported.

April 16th.

CHINA.

(FROM OUR OWN CORRESPONDENT.)

The International Opium Commission, Shanghai.

THE main practical utility of this Commission has been to bring together a vast amount of information as to the growth, manufacture, and sale of opium in various countries. Of its resolutions the most important was that in which the Commission declared that it was not constituted in such a manner as to permit the investigation from a scientific point of view of anti-opium remedies and of the properties and effects of opium and its derivatives. It deemed such investigation to be of the highest importance and desired each delegation to recommend this branch of the subject to its own Government for such action as that Government may think necessary. Another resolution strongly recommended each delegation to move its Government to enter into negotiation with China for the prohibition of the trade and manufacture of such anti-opium remedies as contain opium and its derivatives. It is a great pity that stress was not laid, before the Commission assembled, on the importance of having more medical and chemical expert knowledge in the inquiry. It did not require a Commission to tell us that opium smoking is a widespread evil and that China is making some efforts to grapple with it. What is wanted is a consideration of the best methods of suppression. Legal prohibition of the growth or import is not going to succeed. Smuggling is being irresistibly carried on in every other country (e.g., America, Ceylon, Australia, the Philippines, &c.) where there is a demand for it, and it is so with China. The chief Chinese delegate, Mr. T'ang Kuo-an, proposed:—

---

[1] The case is a corroboration of the paper in THE LANCET of April 17th, by Dr. N. Neild and Dr. E. V. Dunkley.

> That a committee of five delegates be appointed to consider and report on the medical aspects of the opium question, including the best methods of curing the opium habit without recourse to opium and morphine.

In speaking to this proposal Mr. T'ang Kuo-an said:—

> We consider that this question is only second in importance to the suppression of opium in China. We think it would be futile for us to attempt to stop the smoking habit while we continue to use the drug in other ways, such as eating it in the form of pills, &c. Therefore if this Commission is going to justify its existence and is bent on accomplishing results which will be at all satisfactory it is necessary in our opinion that this matter should be fully discussed. To show with what importance the question is regarded by everyone I beg to state that His Britannic Majesty's Minister at Peking has frequently asked our Government what benefit China would derive from restricting the cultivation of opium were the opium evil in other forms (by which he meant the use of opium pills, &c.) to be allowed to be spread all over the Empire.

He added that he begged most earnestly for the coöperation and support of the Commission in favour of his proposal. Unfortunately, owing to the fact that the delegates had no power to exceed their instructions, the Commission was unable to "justify its existence," and this was the rock on which the practical usefulness and the proper aim and object of the Commission were wrecked. An amendment was carried to the effect that the Commission did not include a sufficient number of men competent to deal with the question and emphasised the fact that the Commission was not appointed with a scientific basis. Among the resolutions put forward by the American delegates one was to the effect that "the principle of the total prohibition of the manufacture, distribution, and use of smoking opium is the right principle to be applied to all people—nationals, dependent, or protected"—by each Government. Another resolution stated that "each Government represented is best able to determine what shall be regarded as legitimate medical practice." These did not find favour with the British delegates, who did not see their way, as far as India is concerned, to assent to total prohibition and saw great difficulties in defining what constituted "legitimate medical practice," it being impossible to apply Western medical ethics to a great country like China. It was found during the sittings that the representatives of China were unable to produce trustworthy statistical evidence of the actual extent of the diminution in the production of opium—a fundamental element of the problem of prohibition which will present increasing difficulties. In the inland provinces, which are the greatest opium-producing districts, taxation is irregular and for the most part evaded, and public and official returns are practically unknown. From one of these provinces (Kan-Su in Western China) 3630 piculs more opium found its way down the Yangtze river to Ichang in 1908 than the net import of all foreign opium. A picul is 133 pounds. So much for the work of the Commission, which cannot be said to have been a success, though it has paved the way for a scientific investigation into the best means of eradicating and curing the opium habit.

The Abuse of Opium in America.

As the International Opium Commission owes its inception to America, a few facts concerning the opium evil in that country may be added, from which it will be seen that the United States have a heavy problem of their own to settle. In 1907, 444,121 pounds of crude opium (i.e., for medicinal purposes) and 151,916 pounds of smoking opium were imported. In addition to this it is officially admitted that a large amount is smuggled into the country. The crude opium originates from Smyrna and the Levantine ports, while the islands of Macao and Hong-Kong supply the smoking opium. There are 100,000 to 150,000 smokers among the white and coloured population. Among the general criminal population 15·48 per cent. are smokers, as are 5·62 per cent. of prisoners. An incredible allegation is that 10 per cent. of the medical profession throughout the 25 States are addicts to the use of opium in one form or another. There is an enormous growth of the morphine habit, especially in rural communities. A large percentage of this class have become addicted to the morphine habit largely as the result of a sincere objection to the use of alcohol in any of its forms. From 10 to 20 per cent. of the Chinese population smoke. In every census period in America there has been a per cent. increase in the importation of smoking opium largely in excess of the per cent. increase of the population, and this in spite of the fact that the Chinese population has been practically stationary for 30 years. America intends to do her best to stamp out this growing evil in her midst, and a law has been passed which came into effect on April 1st, 1909, making it unlawful to import smoking opium or opium prepared for smoking, only opium for medicinal purposes being allowed. With regard to her colony in the Philippines, the American authorities have to admit that the ease with which opium is smuggled into the islands makes it impossible to cut off the supply. There never has been any growth in these islands, the chief sources of opium supply being Singapore and Hong-Kong. Of the total number of Chinese residents (55,000) in the Philippines 23 per cent. are registered officially as smokers. Hong-Kong and the Straits Settlements derive a great part of their opium supply from Persia. They take 50 per cent. of the total amount produced annually in that country—viz., 10,000 piculs a year; Europe and Africa take 5 per cent., Great Britain 20 per cent., and the remaining 25 per cent. is for home consumption. The total value of opium exported from Persia is £600,000 per annum. Though opium smoking is not prohibited in Persia, only the lowest classes smoke there.

Peking, March 9th.

Obituary.

THOMAS CRAWFORD HAYES, M.A. T.C. DUB., M.D. DUB., F.R.C.P. LOND.,

EMERITUS PROFESSOR OF OBSTETRIC MEDICINE, KING'S COLLEGE, LONDON; CONSULTING PHYSICIAN-ACCOUCHEUR AND PHYSICIAN FOR DISEASES OF WOMEN, KING'S COLLEGE HOSPITAL; CONSULTING PHYSICIAN FOR DISEASES OF WOMEN, ROYAL FREE HOSPITAL, ETC.

MANY former students of King's College Hospital will have learnt of the death of Dr. Hayes with the deepest regret. It occurred at his residence in Clarges-street, Mayfair, after a long and painful illness. His early studies were conducted in Dublin, where he graduated in Arts, and before leaving was a senior moderator and gold medallist at Trinity College. He entered the medical school at King's College in 1866, when Richard Partridge was teaching anatomy and Lionel Beale held the chair of physiology. It is somewhat curious that before qualifying he had not shown any marked preference for the special branch to which his life later was devoted; his tendency seemed to point rather to medicine than to obstetrics. He was awarded a special certificate in medicine, and after becoming a Licentiate of the Society of Apothecaries, he held office for a year as house physician at King's College Hospital. In the same year he was honorary treasurer of the medical society of the hospital. In 1872 he was elected Sambrooke medical registrar, and later in the year he was appointed assistant physician for diseases of women and children and assistant physician-accoucheur, on the promotion of Dr. W. S. Playfair to the professorship of obstetric medicine. He threw himself into his new duties with characteristic impetuosity, and his class rapidly appreciated the earnest nature of his teaching. Though this was marked by a somewhat dogmatic tone, it was perhaps more impressive than it might have been had he given expression to the different difficulties which so often stimulate further inquiry and research. In these early days he was autocratic in rigidly excluding from his out-patient room all junior students whom he considered were attracted by prurient curiosity rather than by a desire to study, and, it is needless to add, that in this way he was misunderstood by some men. On the other hand, he was unsparing in the time and trouble he devoted to the duties of the maternity department, and was ever ready to come to the rescue when suddenly summoned in cases of difficulty. Always keen on the practical side, he worked for some few years as physician to out-patients at the Evelina Hospital for Sick Children, and subsequently at the General Lying-in Hospital. After 17 years of probation he was appointed lecturer on practical obstetrics at King's College in 1889; a few years later his title was changed to that of professor, and on the resignation of Dr. Playfair he became professor of obstetric medicine and diseases of women. Meanwhile, he had been engaged in similar work at the Royal Free Hospital, and at the time of his death he was a consulting physician of that institution. In 1872 he became a Member of the Royal College of

Physicians of London, and in 1889 he was elected a Fellow, while he was for some time examiner in midwifery at the English Conjoint Board. In 1893 he was made a Fellow of King's College.

Dr. Hayes was of a retiring disposition in every way. He published no signed contributions, but his teaching was always carefully prepared, his delivery good and clear, and his thorough mastery of practical details carried conviction. Like most shy men, he was perhaps too prone to take offence and to imagine some slight or rudeness where none had been intended, but the storm was soon over and he resumed cordial relationship with a charming facility. He was at his best and brightest when surrounded by a sympathetic audience at friendly gatherings of present and former students, when he would pour out a fund of fun and anecdote that seemed to be inexhaustible. For many years he undertook the duties of honorary secretary to the dinner of former students, and his geniality and persuasive charm contributed largely to the success of these gatherings. Had he devoted himself more to literature than to the practical work of his numerous hospital appointments he would no doubt have been more widely known, but it may be doubted whether this would have added in any way to the appreciation of his students, upon whose affection he felt he could rely.

FREDERICK ERNEST WEBB, M.R.C.S. ENG., L.S.A.

THE death is announced of Mr. Frederick Ernest Webb on April 8th at the age of 77 years. He died at his residence, 113, Maida Vale, where for nearly 60 years he and his father had carried on one of the most successful general practices in London. Some weeks ago Mr. Webb had an attack of influenza, and for some time hopes were entertained of his recovery as the more unfavourable symptoms passed away; he, however, sank into a condition of complete unconsciousness, which continued for some time prior to his death. In him has passed away a typical old family doctor, a class which is yearly becoming smaller—men trusted often by two or even three generations of the same family. In him also the medical profession and the cause of medical science have lost an open-handed and practical friend.

Frederick Ernest Webb was a grandson of Thomas Stallad Webb of the Manor House, Coltishall, in Norfolk, a cadet of the old family of Webb of New Sarum, in Wiltshire, and was the only son of the late Thomas Ernest Webb and his wife Eleanor, the second daughter of the late John Venn of Highbury Park. His father, prior to his settling down in Maida Vale about the year 1850, carried on a large practice at Bungay in Suffolk, and there his son was born on August 28th, 1831. After being educated privately by the rector of a neighbouring parish, he passed some time with his father, and then, at an early age, he entered as a pupil at the Norwich Hospital, where the late Mr. Cadge, who was a connexion, was then the chief surgeon. There he passed two years, gaining much useful surgical knowledge; he was for at least a year the only pupil and had the whole of the surgical dressings to apply. From Norwich he proceeded to St. George's Hospital, the school of which he entered on his father settling in practice in Maida Vale. He completed his course of hospital study in 1854, and in that year he was enrolled a Member of the Royal College of Surgeons of England. In the following year he proceeded L.M. at the College and took out the Licence of the Apothecaries' Hall.

On obtaining his first qualification, in 1854, he at once joined his father in practice and with him he worked until their partnership was dissolved a few years before the elder partner's death, which occurred at the age of 74 years in the August of 1875. The years which followed the termination of his partnership with his father were the most strenuous of his life; although a general practitioner, he was also a surgeon and gynæcologist, undertaking often the most serious operations. His practice grew until it became one of the largest and most lucrative of the general practices in the West-end of London. Mr. Webb, when in his prime, would often after a busy day take a night journey to see some wealthy patient in the country. He often said that he never lost the confidence of a patient, and the regard in which he was held is exemplified by the circumstance that although he was for the last years of his life almost only a nominal partner in the firm of "Webb, Walker, and Adams," yet to within a short time of his death he saw some of these old patients professionally, so that he can be said to have died in harness. One of his chief friends in the days when he was working alone and at high pressure was the late Sir William Jenner, and by his advice it was that he took Mr. J. R. Walker as a partner, while some years later a third partner was taken into the firm, Dr. G. E. D'Arcy Adams.

In his busy and successful life Mr. Webb gave much of his time to the cause of charity. He was for many years honorary medical officer to the Home for Female Orphans in St. John's Wood and to the Hospital and Home for Incurable Children in Maida Vale (now located at Hampstead). On retiring from active work at the latter institution he was appointed consulting medical officer and he presented a sum of money to endow a bed in perpetuity. Of the former institution he was for long one of the vice-presidents. In March, 1901, he gave a donation of £1000 to the charity, which sum the governors invested and called the Webb Presentation Fund "in gratitude for Mr. Webb's many acts of kindness and valuable services to the institution for 36 years." Mr. Webb was always devoted to his hospital and school, St. George's, and had among its staff many old and tried friends. Ever delighting at the progress which had been made during his long life in the science of medicine, and in order to encourage the younger men, early in 1895 he presented to the medical school the sum of £1000 to found an annual prize in bacteriology to foster work in the new science which he saw meant so much to suffering humanity.

Apart from his professional life and public sympathies, Mr. Webb possessed a charming personality. He was very well known as an accomplished amateur musician; he played the violin, piano, and organ and was for long a member of the Royal Amateur Orchestral Society, of which the late Duke of Saxe-Coburg, as Duke of Edinburgh, was a member. Mr. Webb was the possessor of some very fine old violins and of a viola which had been given to his grandfather, Thomas Stallad Webb, by King George III. He also possessed con-[illegible] matters; he counted some of [illegible]s friends and patients, [illegible] their work. His home in Maida Vale was ever a centre of hospitality and the dinners, at which he entertained his professional friends, were delightful reunions. At these dinners there gathered round his table, among other friends, Sir James Paget, Sir William Jenner, Sir Joseph Fayrer, and Sir William Broadbent, and sometimes Frank Buckland, who had been his host's friend since his boyhood, and who added much to the enjoyment by his wit and utter disregard of the conventionalities of life. Frederick Webb was from his boyhood a keen sportsman and a first-class small-game shot; every year he passed a portion of the autumn and as many week-ends as he could spare either at a shooting which he rented near Berkhamsted, or in later life in Sussex, where for many years he rented a house called Loxwood and some very good shooting. He was also a fair billiard player, and during his latter years, when he could no longer see well enough to shoot, he devoted some hours each day to the game, either at the Constitutional or more often at the Oriental Club, of both of which he was for many years a member. This pastime was interrupted by the formation of double cataract a few years ago, but both eyes were most successfully operated on by Mr. H. E. Juler, and he was able, much to his joy, to resume his recreation at his clubs.

He married on August 28th, 1860, at St. Saviour's Church, Paddington, Mary Anne, only daughter of the late Mr. John Grafton, C.E., of Blomfield-crescent, W. He has left a widow, two daughters and a sister, Mrs. Thomas Fuller of Rugby, to mourn his death. He was buried on the morning of Tuesday, April 13th, at Highgate Cemetery; his cousin, the Rev. William P. Webb, M.A., rector of Ashwell, Herts, read the chief part of the service, in which Canon Duckworth and Canon Syers also officiated.

EDWARD RECKITT, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

ON March 24th last Edward Reckitt, one of the few remaining pupils of Sharpey and Liston, died at his residence, Beech House, Wainfleet, [illegible]shire, in his eighty-eighth year. He commenced the [illegible] elder Dr. Lunn of [illegible] of the Hull School of Medicine and the practice of Hull General Infirmary from 1843 to 1845. In the latter year he proceeded to University College, London, attracted thither by the fame of Liston, and continued his studies there until 1846, when he qualified as M.R.C.S. Eng. and L.S.A. Whilst at University College Hospital he dressed for Liston and was ever afterwards a great admirer of that renowned surgeon. After qualifying at the age of 25 years, Reckitt returned to Hull, where his father and other members of the family, including his cousin Sir James Reckitt, the present head of the family, resided. Starting in general practice, he soon obtained a firm footing and was appointed lecturer on botany at the Hull School of Medicine and surgeon to the Hull and Sculcoates Dispensary. Under the stress of hard work his health gave way and in 1856 he purchased the practice of Dr. Kirkham Burton of Wainfleet, and here he continued to work for 40 years, retiring in 1896 after an attack of cerebral thrombosis resulting in partial paralysis of the right arm and leg, from which he never entirely recovered. Whilst in practice at Wainfleet he enjoyed the confidence of his patients to a remarkable degree. He rarely took a holiday. Particularly fond of surgical work, he necessarily performed many severe operations, and much of this work was done single-handed or with the help of only an untrained nurse. Called on one occasion to a case of wounded palmar arch, caused by the bursting of a shot gun and in which recurrent hæmorrhage supervened, he ligatured the brachial late at night by the light of lamp, single-handed and without the aid of an anæsthetic. His self-reliance and courage in emergencies—qualities so often needed in the life of the busy country surgeon—were marked characteristics in his work, and equally so his sound common sense and tact in dealing with those who sought his advice. For nearly 40 years he held the appointment of medical officer of the Wainfleet district of the Spilsby Union and surgeon to the coastguard. He was also for many years president of the Literary Institution. His fatal illness was of short duration, as he was out as usual until March 14th, when he caught a chill. Bronchitis resulted and he slowly sank from exhaustion, conscious almost to the last of the presence of those members of his family who could be with him. He died in the house in which he was born and which had been the home of his grandfather more than a century before. He leaves three sons, all of the medical profession—Dr. E. B. Reckitt of Boston, Lincolnshire; Lieutenant-Colonel J. D. T. Reckitt, late of the Royal Army Medical Corps and now staff officer to the A.M.O. 1st London Division T.F.; and Mr. W. F. Reckitt of London.

HENRY STILWELL, M.D. EDIN., M.R.C.S. ENG., L.S.A.

THE death is announced of Dr. Henry Stilwell, which took place at Eastbourne on April 12th, at the age of 73 years. He was a son of the late Mr. James Stilwell, F.R.C.S., of Uxbridge. Educated at Rugby, he entered the medical profession by apprenticeship to his father. He became later a student at St. Bartholomew's Hospital on Oct. 1st, 1853, and proceeded to Edinburgh to attend the lectures and complete his studies. He was admitted a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries in 1857, taking the degree of Doctor of Medicine at the University of Edinburgh in the same year, at the early age of 21 years. After a voyage to Australia he was called upon to assist his father in general practice for two years in his native town, but relinquished it to join his cousin in the management of the asylum in that district. At Moorcroft, Hillingdon, he spent the greater portion of his life, having acted as medical superintendent of that institution for 45 years. He retired in 1906 to live at Eastbourne, where he died after a short illness.

Dr. Stilwell was a man of sterling qualities and a good specimen of the English country gentleman—a man of wide culture and with varied interests in life. In the "seventies" and "eighties" he was a well-known figure in the hunting field. In later years he had taken to golf as a recreation. Until recently he was a regular attendant at the St. Bartholomew's Hospital decennial dinners and at the dinners of the Edinburgh University Club, and was known to a wide circle of medical friends. Of a somewhat reserved disposition, he did not often enter into discussions at the ordinary medical societies, but he was an old and valued member of the Medico-Psychological Association, which he joined in 1862. He was also a frequent attendant at the metropolitan meetings of the British Medical Association. For years he was the local secretary of the Epsom College Benevolent Fund, in which he took a great interest. In his own special department his opinion was sound and practical. Those who have been closely associated with him learnt much from him and found that under the cloak of his somewhat austere manner was concealed one of the kindest hearts. He had also a fund of humour about him and was able to tell a good story.

Feeling the responsibility of his position in the care of the insane he entered into the lives of his patients and by his example induced others to do their utmost to promote their recovery. He was much liked by his patients and respected by all who knew him. Dr. Stilwell leaves a widow, a son, and three daughters to mourn their loss. The funeral took place at Hillingdon on April 16th in the presence of his son and sons-in-law, and many others.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Georg Schuldheis, formerly *docent* of psychiatry in the University of Upsala.—Dr. Dillon Brown, professor of children's diseases in the University of Vermont.—Dr. Pedro Almeida Magalhães, professor of medical pathology in the University of Rio de Janeiro.—Dr. Granier, a well-known and very popular medical councillor in Berlin.—Dr. A. Friedlowsky of Vienna, a former prosector under the eminent professor of anatomy, Dr. Hyrtl. His age was 74.—Dr. E. Kufferath, professor of clinical midwifery in the University of Brussels.—Dr. V. F. Voskressenski, professor of clinical surgery in the University of Kharkoff.—Dr. Karl Hotz, formerly professor of ophthalmology in the Rush Medical College, Chicago.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on April 15th, the following gentlemen were approved:—

Harold Ernest Bloxsome, Durham University and St. Bartholomew's Hospital; Algernon Edgar Percy Cheesman, Guy's Hospital and private study; William Noel Child, M.A. Cantab., Cambridge University and St. Thomas's Hospital; John Stanley Cocks, Guy's Hospital; Anthony D[illegible] phen Ormon Dolan, Leeds Univers[illegible] y's Hospital; Aubrey Scott Gillett, [illegible] Noel Hodges, B.A. Cantab., Cambrid[illegible] ital; Herbert Arnold Lake, M.R.C[illegible] spital; John Rhodes Liddell, She[illegible] ichard Neil [illegible] illip Stanley [illegible] Findlin Maw, [illegible] University; John Francis O'Malley, L.R.C.P.I., L.R.C.S.I., L.M. Dublin, [illegible] Middlesex [illegible] Clinton Palmer, St. Mary's Hospital; [illegible] Roe, St. [illegible] Hospital; [illegible] B.A. [illegible] versity and [illegible] Hospital; [illegible] Taylor, Guy's Hospital; Percy Boyd Wallis, Cambridge University and St. Bartholomew's Hospital; John Murray Weddell, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Arthur Donald John Bedward Williams, B.A. Cantab., Cambridge University and Guy's Hospital; and Leslie Douglas Wright, Guy's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna*: Dr. Gino Norsa and Dr. Giuseppe Poggi have been recognised as *privat-docenten* of Internal Pathology.—*Bonn*: Dr. Karl Vogel, *privat-docent* of Surgery, has been granted the title of Professor.—*Breslau*: Dr. Bruck has been appointed Chief Medical Officer of the Dermatological Clinic in place of Professor Zieler who goes to Würzburg.—*Cornell*: Dr. Graham Lusk, of the University and Bellevue Hospital Medical College, has been appointed to the chair of Physiology.—*Cracow*: Dr. Stanislaus Anton Braun, *privat-docent* of Midwifery and Gynæcology, has been granted the title of Extraordinary Professor.—*Freiburg*: Dr. K. Gauss has been recognised as *privat-docent* of Gynæcology and Midwifery.—*Halle*: Dr. Richard Freund, *privat-docent* of Gynæcology, has been granted the title of Professor.—*Harvard*: Dr. Charles V. Chapin has been appointed Lecturer on Hygiene.—*Heidelberg*: Dr. Arnsperger, *privat-docent* of Medicine, has been granted the title of Professor.—*Königsberg*: Dr. Walter Kruse of Bonn has been appointed Professor of Hygiene in succession to Dr. Pfeiffer.—*Moscow:* Dr. N. J. Pobiĕdinski, *privat-docent* of Midwifery and Gynæcology, has been appointed Extraordinary Professor.—*Naples:* Dr. Pio Marfiori of Pa [illegible] fessor of Materia Medica and [illegible] —*Prague (Bohemian University)* [illegible] Dr. Josef Znojemski have been recognised as *privat-docenten* of Surgery.—*Rome:* Dr. Luigi Tomellini has been recognised as *privat-docent* of Forensic Medicine.—*Vienna:* Dr. Alfred Exner has been recognised as *privat-docent* of Surgery.—*Würzburg:* Dr. Karl Zieler of Breslau has been appointed Extraordinary Professor of Dermatology.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—A course of eight lectures on the Experimental Evidence relating to Variation and Heredity and its bearing upon the Problems of Evolution will be delivered by Mr. George P. Mudge, lecturer on biology, commencing on Tuesday, May 4th, and following Tuesdays at 10.30 A.M. The lectures will be delivered in the Biological Theatre of the college. All students of the University are free to attend. Members of the profession will be admitted on presentation of their address cards.

THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—On April 20th H.R.H. Princess Alexander of Teck opened the new out-patient department and nurses' home for 50 nurses in connexion with the Royal National Orthopædic Hospital in Marylebone. The hospital, which has entrances in Bolsover-street and Euston-road, is the outcome of the amalgamation of the late National Orthopædic Hospital, Great Portland-street, upon the site of which the new hospital is in course of erection, with the Royal Orthopædic Hospital, Oxford-street, and the City Orthopædic Hospital, Hatton Garden. The in-patients of these institutions are at present housed in Charing Cross Hospital, but the Royal National Orthopædic Hospital will, when completed, contain 213 beds for their reception. King Edward's Hospital Fund has granted £10,000 towards the new buildings, besides an annual contribution of £2000.

THE SEASIDE CAMPS FOR LONDON WORKING BOYS.—An admirable association every year sends away to a seaside camp for a week or fortnight's holiday a large number of London working boys. The camp is held at Bexhill, and last year as many as 2917 lads were sent away, that number being 400 in excess of the number sent in 1907. The amount of good done by this society is undoubtedly very great. Were it not for the camps organised by this and other institutions many a lad would spend his holiday in loafing about the streets from sheer inability to afford the expense of getting out of town. And besides the physical advantages of good food and clean air which the camp affords, there is also the inestimable benefit of being under discipline, an advantage which the working lad, compared with the boy of the upper classes, seldom gets. The latter when he goes to a public school finds himself under a discipline which is most beneficial. He learns at first that he is not as good as or better than anyone else, but that he is quite inferior. As he gets older he finds that he is improving and finally, having served, he learns to rule. But a board school education does not teach this. Seaside camps, then, are a valuable method of training and deserve all support. Every boy who is admitted has to contribute according to his means towards expenses, but of course that is of necessity only a small part of the actual cost. Contributions may be sent to the secretary, Mr. P. Abel Bloxham, 23, Northumberland-avenue, London, W.C., or to Messrs. Cocks, Biddulph, and Co., 43, Charing Cross, London, W.C.

PORTHCAWL REST.—While on the north coast of Wales there are several well-equipped convalescent homes, there is only one, that at Porthcawl, in the southern counties of the Principality. The reason for this is, no doubt, to be found in the fact that whereas the majority of those who make use of the northern institutions come from the midland counties of England, even as far distant as Birmingham, the number of persons who go to the Porthcawl Rest from the English counties is very small indeed. In 1908, of the 1335 patients treated there only 27 came from outside South Wales. The Rest was founded in the year 1878, when 33 patients were admitted, and year by year it has been necessary to find accommodation for an increasing number. So popular indeed has the institution become that the managing committee has had to make a rule that except in special circumstances a patient cannot be admitted who has been in the Rest during either of the two previous years. Before this rule was made a large number of "annual visitors" kept out urgent convalescent cases or those who had never been in the home before. The institution is managed upon very economical lines, for the weekly cost per patient during 1908 averaged only 10*s.* 9*d.*, and the cost of food, fuel, and washing was less than 7*s.* per patient weekly. Enlargements are now being carried out at a cost of some £9000, towards which sum all but £2500 have been subscribed, but with such a record of useful service there ought to be no difficulty in securing that amount.

HOSPITAL SATURDAY FUND.—The annual public meeting in support of the Hospital Saturday Fund was held at the Mansion House on April 17th, Sir Savile Crossley being in the chair in the absence of the Lord Mayor. The chairman said that "records" had been achieved during the past year in the amounts collected and distributed and in the reductions of working expenses. The income of the Hospital Saturday Fund last year was £29,830, of which 199 London firms had each collected £25 or upwards. He suggested that some of the 200 empty hospital beds in London might be opened to paying patients. Canon Horsley moved the adoption of the report, which was seconded by the Mayor of Finsbury and carried. Dr. T. D. Acland proposed a resolution approving the measures taken for the prevention and treatment of tuberculosis by the Hospital Saturday Fund, which had devoted a sixth of its income to those objects. He urged upon the supporters of the Fund the importance of giving advanced cases of the disease a place of refuge apart from the Poor-law institutions. Dr. A. P. Gibbons, in seconding, remarked that the Government should be more active in inspecting meat and dairies, and Dr. T. Gambier also supported the resolution, which was carried.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The annual provincial meeting of this society will be held at Torquay on Saturday, May 8th, at 4.30 P.M. A reserved corridor carriage will leave Paddington station on the 11.50 train. Owing to the exertions of members of the council residing at Torquay and of the medical profession of Torquay excellent arrangements of an inexpensive character have been made for the reception of Fellows and guests at the Grand Hotel. An attractive programme has been arranged for the following day, when members will have the opportunity of visiting the South Devon Moors or of playing golf at Stover. Fellows may bring ladies of their family as guests and are also allowed to bring medical guests, for whom the hotel expenses will be charged at the same rate as for the Fellows—namely, one guinea each from Saturday afternoon to Monday morning, including all meals (excepting lunch on Sunday). It is anticipated that there will be a very large gathering of Fellows, and they are requested to communicate with one of the honorary secretaries, Dr. S. Sunderland, 11, Cavendish-place, London, W., and Dr. F. A. de T. Mouillot, Eton House, Harrogate, at once as to the probability of their being present, and to give notice to the hotel if they wish to take advantage of the inclusive terms already mentioned.

SANITARY ASSURANCE ASSOCIATION.—The twenty-eighth annual meeting of the Sanitary Assurance Association was held on April 19th at the offices, 7, Pall Mall, the Presi [illegible] who [illegible] subm [illegible] criticise the sanitary arrangements at the Franco-British Exhibition, and efforts were made to obtain a sanitary section, though without success. But the association itself exhibited plans, illustrative of its work, for which the international committee of judges had awarded a gold medal. On the subject of the exhibition the report said: "The authorities were slow to admit that the sanitary arrangements were other than satisfactory, but thanks to the *Times*, THE LANCET, and other papers, the sanitary condition of the exhibition continued to be the subject of much criticism up to its close, and some improvements were made, though they were far from adequate. The President of the Local Government Board himself looked into the matter and promised in the House of Commons that he would not lose sight of the subject. It may be reasonably hoped that adequate lavatory accommodation will be provided in future exhibitions." The chairman proposed the adoption of the report, which was seconded by Sir William Chance, and carried unanimously. Mr. Mark H. Judge proposed, and Mr. F. A. Gane seconded, the re-election of Sir William Chance and Dr. Hugh Roger-Smith as members of the council, which was carried.

INSTITUTE OF CHEMISTRY.—In the March and April examination in the chemistry of food and drugs, and of water, the following passed: T. Cockburn, C. E. C. Ferrey, P. A. W. Self, B.Sc. Lond., and F. F. Shelley.

THE London County Council has resolved and ordered that Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious disease, shall apply, in the Administrative County of London, to the diseases known as glanders, anthrax, and hydrophobia in man. The Order, which has been duly approved by the Local Government Board, will come into operation as from and including April 26th.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. T. Torkington Blease, M.R.C.S. Eng., L.S.A., who is the medical officer to several societies to which he was appointed 52 years ago, has recently resigned his appointment as medical adviser to the Great Central Railway Company's Provident Society (Altrincham District) after 45 years' service. As a mark of their esteem for Mr. Blease the members of the society have presented him with an illuminated address.

THE LATIN-AMERICAN MEDICAL CONGRESS.—During the month of January a meeting was held in the buildings of the National University of Asuncion. The meeting was composed of medical men and had been called by Dr. William Stewart for the purpose of forming a national committee to deal with the best way of making known the forthcoming Latin-American Medical Congress and the International Hygiene Exhibition which is to form an annex thereto, so that Paraguay might take a worthy part therein. The congress will be held in Rio de Janeiro throughout the first week of August. The Paraguay committee will be constituted as follows:—President: Dr. William Stewart. Vice-President: Dr. Juan B. Benza. Secretary: Dr. Manuel Perez. Members: Dr. Fernando Garitti, Dr. Cayetano Masi, Dr. Luis Zanotti Cavazzoni, Dr. Justo P. Vera, and Dr. Eduardo A. Romero y Bartolomé Coronel. These congresses, which are held every two years, are attaining great proportions and are awakening an interest which is a stimulant to the progress of the medical sciences in Latin-American countries. The first congress was held in Santiago, the second in Buenos Ayres, the third in Montevideo, and the fourth, as mentioned above, is to be held in Rio de Janeiro.

UNIVERSITY OF OXFORD.—The Master and Fellows of University College, upon the report of the examiners, have awarded the Radcliffe Prize for 1909 to Arthur F. Hertz, D.M., Magdalen College, assistant physician, Guy's Hospital, for his dissertation upon "The Physiology and Pathology of the Movements of the Intestines." The College desires to call attention to a statement in the report of the examiners to the effect that original work, in each case fully worthy of the prize, was submitted by the following candidates: Alexander G. Gibson, D.M., Christ Church; and Arthur C. Inman, B.M., M.A., Wadham College. The next award of the prize will be in 1911.—At a meeting of the Radcliffe electors Martin William Flack, B.M., M.A., Keble College, demonstrator in Physiology at the London Hospital, was elected to a Fellowship under the trust on the report of the examiners.—The summer dinner of the Oxford Graduates' Medical Club will take place on Thursday, May 20th, at the Hotel Cecil. The chair will be taken by the President, Sir W. S. Church, Bart., K.C.B., and among the guests who have accepted the club's invitation to attend are: The Chancellor of the University, the Master of University College, the Rector of Lincoln College, the Provost of Queen's College, and the two University Members of Parliament.—Six lectures on the History of Greek Medicine up to the age of Hippocrates will be delivered at the Examination Schools by Joseph F. Payne, D.M., Hon. Fellow of Magdalen College, on Wednesdays and Fridays at 5.45 P.M. beginning on May 5th.

ASSOCIATION OF MEDICAL MEN RECEIVING RESIDENT PATIENTS.—The annual general meeting of this association was held on April 14th at 26, Bryanston-street, W., Dr. T. Whitehead Reid in the chair. Dr. G. E. J. Crallan was elected President for the ensuing year, and Dr. Dove, Dr. Haynes, Dr. Still, Dr. Reid, and Dr. Walsh, Vice-Presidents. The annual report presented by the secretary was read and received. It showed a very satisfactory increase in the work of the association, the number of patients placed being nearly double that of 1907. The demand for membership, however, was shown to continue to be higher than is commensurate with the applications received from patients. The report showed that in spite of this encouraging evidence the association was far from receiving the support which it deserves at the hands of the profession as being an organisation of medical men formed for the purpose and established on the principles of self-help and mutual support; also that it had nothing in common with commercial agencies, as any profits made became the property of the association as a whole. The financial position which enabled the subscriptions to be lowered last year shows that in spite of this fact, and with increased advertising and clerical expenses, the balance brought over at the end of 1908 was almost double that of 1907. Votes of thanks to the chairman and honorary secretary brought the meeting to a close.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The End of the Easter Holidays.

THE House of Commons resumed on Monday, April 19th, after the Easter holidays. However, for the first two days after the resumpt of business the proceedings were very quiet. The number of questions on the notice paper was small and none of them attracted much interest. It was the middle of the week before the normal Parliamentary activity was reached, as Members wherever possible prolonged their holidays for a day or two. The House of Lords resumed on Tuesday, April 20th.

Asylum Officers' Superannuation Bill.

A Select Committee of the House of Commons to take evidence bearing on the Asylums Officers' Superannuation Bill has been nominated. It consists of Sir WILLIAM COLLINS, Mr. HAZLETON, Mr. JOHN HENDERSON, Mr. HORNIMAN, Mr. W. PRIESTLEY, Mr. T. RICHARDS, Mr. ROCH, Mr. STANIER, and Sir JOHN BATTY TUKE.

Street Accidents Caused by Vehicles.

The return showing for England and Wales the number of accident resulting in death or personal injury known to the police to have bee caused in streets, roads, or public places by vehicles during the perio from May 1st to Dec. 31st, 1908, is detailed and elaborate. The grand total of these accidents is 17,973, of which 746 had a fatal termination Motor-cars and motor cycles were responsible for 4499 accidents, o which 198 proved fatal. Motor omnibuses caused 1156 accidents, o which 50 resulted in death.

Deaths of Infants in Poor-law Institutions.

A memorandum by the Local Government Board on deaths among infants in Poor-law institutions has been submitted to the House o Commons. The general conclusion of the memorandum is that all th information in the possession of the department goes to show that, with exceptions which are comparatively few and decreasing, the condition o the Poor-law maternity wards is satisfactory, and that as regards the young children one of the most striking features of the ordinary Poor law nursery is the healthy appearance of the "permanent" children a compared with the newcomers.

The Medical Acts Amendment Bill.

Opposition will be offered to the Medical Acts Amendment Bill if a attempt is made by Mr. COOPER to obtain a second reading for hi measure. Six motions for the rejection of the Bill have been put down on the order paper. These motions stand in the names of Mr. JOYNSON HICKS, Mr. WILES, Mr. ESSEX, Sir HENRY KIMBER, Sir HENRY COTTON and Mr. GEORGE GIBBS

HOUSE OF COMMONS.

WEDNESDAY, APRIL 21ST.

The Return of Tuberculous Patients from Canada.

Mr. WEIR asked the President of the Board of Trade whether, havin regard to the fact that under Canadian law emigrants from this countr who developed consumption within two years after arrival in Canad were required to return, he was now in a position to state what precau tions had been taken by steamship companies, in vessels sailing fror Canadian ports to the United Kingdom, to isolate consumptiv passengers in such a way as to prevent other passengers running th risk of infection.—Mr CHURCHILL replied: The steamship companie inform me that persons returning from Canada on account of con sumption are carefully isolated during the voyage and kept apart fron the other passengers.

BIRTHS.

BURGESS.—On April 14th, at Milverton Lodge, Victoria Park, Manchester, the wife of Arthur H. Burgess, of twin sons.

[illegible] oad, Oxford, the wife of [illegible]

[illegible] Fairlight, Hampton Hill, [illegible] B.A., M.D., L.R.C.P., of a daughter.

MACLEAN.—On April 18th, at Tollington Park, N., the wife of Kenneth Maclean, F.R.C.S., L.R.C.P. Edin., of a son.

MARRIAGES.

BURRIDGE—CURTIS.—On April 20th, at St. Joseph's, Highgate Hill, Henry Alfred Burridge, B.A., Trinity College, Dublin, M.R.C.S. [illegible] L.R.C.P. Lond., to Adine Marie, elder daughter of R. L. [illegible] ge Hall, Essex.

[illegible] Christ Church, Lancaster-gate, [illegible] M.S., F.R.C.S., to Florence [illegible] late Arthur Grame Ogilvie, of [illegible]

GRANT—KINGHAM.—On April 17th, at St. Cuthbert's Church, West [illegible] youngest daugh [illegible]

POPE—GRAVENER.—[illegible] Charles Alfred [illegible] Gravener, eldest daugh [illegible] (retired).

DEATHS.

FRASER.—On April 13th, at Tettenhall road, Wolverhampton, John Fraser, M.D., aged 89 years.

NUNN.—On April 13th, at The Gaunt Tower, Kneesworth, Royston, Thomas William Nunn, F.R.C.S.

STILWELL.—On April 12th, at Hanover Lodge, Eastbourne, Henry Stilwell, M.D., aged 73 years.

TAYLOR.—On April 13th, at his residence, Beechwood Hall, Mapperley, Nottingham, Charles Bell Taylor, M.D. Edin., F.R.C.S.E.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN SWAZILAND.

Mr. R. Clark Perkins, Government Medical Officer of Swaziland, in his report for the year 1907-08, which has just been received at the Colonial Office and presented with other papers to Parliament, states that during the period under review there were admitted to the Government Hospital at Mbabane 39 patients, whilst the out-patients numbered 1275. The hospital accommodation is poor, but steps are being taken to improve it. The native does not, as a rule, avail himself to any great extent of the medical treatment provided for him, preferring to be attended by his own medicine man. The greatest use he makes of the hospital is for the extraction of teeth and the dressing of wounds. Latterly, however, there has been an increase of attendance for ordinary ailments, and as education and white influence advance greater advantage will no doubt be taken of the opportunities afforded in this direction. The majority of wounds dealt with are caused by knobsticks or spears. The natives are a peaceable and law-abiding race until the season for beer arrives—i.e., the winter—and if some restrictions were imposed upon the making of the drink there would be fewer cases of murder and serious wounding. In about 75 per cent. of the post-mortem examinations made death was due to wounds or injuries received during or after a drinking bout. Swaziland is, roughly, divided longitudinally into three regions, the higher, middle, and lower. The higher region is from 4500 to 3000 feet; the middle from 2000 to 1500. Both these regions are healthy. In the lower or bushveld region malarial fever is prevalent amongst white and black; particularly was it so during the end of 1906 and the beginning of 1907. A few cases of contagious conjunctivitis were treated in hospital; on occasions whole kraals suffer from this disease. Only two cases of tuberculosis came under treatment, but this cannot be taken as giving a fair estimate of the prevalence of the disease. No small-pox has been reported during the year. The natives have learnt to appreciate the value of vaccination, and it is hoped to carry out systematic vaccination yearly. On one occasion the whole of the Royal kraal, including the young paramount chief, underwent the operation. Syphilis is very widespread indeed. Owing to the great expense of carrying out quarantine regulations the disease is difficult to cope with, and persons suffering from this complaint have every facility for spreading the infection. Some cases have been treated in hospital, but the great majority at their own kraals, where the only thing that can be done to prevent the spread of the disease is to point out the risk of communicating it to others. Every opportunity is taken of warning the natives of this danger. There are a few known lepers in the country, but with the precautionary measures taken it is not anticipated that there is any danger of the disease spreading. There has been a severe epidemic of whooping-cough during the year, whites and natives suffering alike. Amongst the former there were two deaths, but no record is obtainable of the deaths among the natives, though the mortality is known to have been large, even among those under treatment. The natives, as a rule, respond to surgical treatment much better than to medical. Diseases of the lungs are particularly fatal to them. Under the heading of diseases of the skin, ulcers and scabies make up the great majority. For midwifery the natives have their own practitioners, whose methods are of the rough-and-ready description. The Swazi appears to have a knowledge of drugs, and not infrequently gets rid of the fruits of illicit love. One drug used in cases of diarrhœa is most effective. There is no laid-on water-supply in Mbabane, but an abundant and pure supply is available. The sanitary system has been much improved, dry earth-closets being in use in the village, gaol, and police camp. The general public health has been good. The census return shows the European population at 890, and the native population at 84,529.

THYMOL IODIDE AND FERROUS SULPHATE IN THE TREATMENT OF CHRONIC ULCERS.

IN the *Military Surgeon* for April Dr. Mark J. White recommends the use of a dusting powder, containing equal parts by weight of thymol iodide and dried ferrous sulphate, in the treatment of chronic ulcers of the skin. After washing the ulcer with carbolic lotion and removing all crusts from the borders the surface is dried and covered with the powder. As soon as the ferrous sulphate produces a burning sensation the excess of powder is blown off, leaving only a thin adherent film, which is covered thickly with zinc ointment and protected by gauze, strips of adhesive plaster, and a bandage. The dressings should be renewed every 48 hours, care being taken to avoid an excess of the powder which would cause severe pain. Any acute inflammation of the surrounding tissues should first be treated by means of moist antiseptic dressings. If the ulcer is so large that more than six or eight applications of the powder are required its use should be interrupted for four or five days and only the zinc ointment applied in order to avoid over-stimulation of the granulations. This dusting powder is applicable to all varieties of chronic ulcerations of the skin, regardless of their etiology, and it is very serviceable in the treatment of slowly healing bubo-extirpation wounds that so frequently keep men off duty and in hospital for a long time.

J. A. S.—We cannot state exactly what view the General Medical Council would take of the situation if it were brought to its notice, but it is quite likely that a medical man holding such a post might be asked to sever his connexion with the medical profession. Our own opinion is that a medical man should not place himself in such a position as that described by our correspondent.

M.D.—The terms are not necessarily synonymous, but we shall be happy to publish a letter on the matter from our correspondent, if the initials which he adopts are supplemented by his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—H. W. Trewby, D. P. Gabell, J. Howard Mummery): at 8 P.M.

Paper:

Mr. Harold Simms: Some Experiments on the Action of Formalin and Other Root Dressings.

Casual Communication:

Mr. Harold Chapman and Mr. Ernest Rock Carling: A Case of Round-celled Sarcoma of the Lower Jaw. (The patient will *attend at 7.30 P.M.)*

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Herbert P. Hawkins, A. M. Gossage): at 5.30 P.M.

Paper:

Dr. O. K. Williamson: Clinical Observations on the Influence of the Vessel Wall on (so-called) Arterial Blood-pressure Readings.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Raymond Johnson, H. D. Rolleston): at 8 P.M.

Cases:

Mongols and Conditions that have been Confused with Mongolism—Dr. L. G. Guthrie, Dr. Sutherland, Dr. Morley Fletcher, Dr. Poynton, Dr. Langmead, and Dr. Harry Campbell.

Mr. J. Jackson Clarke: Cases of Congenital Hip Disease treated [illegible]

Mr. [illegible] ubcoracoid Dislocation [illegible] ure of Humerus, [illegible]

Dr. [illegible] rauma.

Dr. [illegible] the Extremities in [illegible] Edema.

Mr. [illegible] Coxa Vara treated by [illegible]

Mr. H. [illegible] W. H. Bowen: Hereditary Transmi[illegible] Foot in Mother and Child; Mother shown at the Clinical Society in 1887.

Paper (at 9.40 P.M.):

Mr. W. Fedde Fedden: Six Cases of Infective Gangrene of the Extremities.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—Clinical Evening. Cases will be in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. Keith: On Specimens of Cleft Palate and Malformations of the Tongue. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin).

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that *only those subscriptions* which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) *do* not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Lumleian Lectures

ON

RHEUMATIC FEVER AND VALVULAR DISEASE.

Delivered before the Royal College of Physicians of London on March 23rd, 25th, and 30th, 1909,

By NORMAN MOORE, M.D. Cantab., F.R.C.P. Lond.,

SENIOR CENSOR OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE II.[1]

Delivered on March 25th.

Valvular Disease.

Mr. President, Censors, and Fellows of the College,—It is remarkable that neither in the notes of the Lumleian lectures of 1616, in which Harvey shows that he had attained the conception of the circulation of the blood, nor in his "Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus" of 1628, in which his discovery is fully set forth, is there any allusion to valvular disease. The retardation of the blood in the veins produced by narrowing of the mitral orifice with the consequent dropsy seems to us an illustration of the course of the blood from the right heart through the lungs to the left auricle, and the changes in the pulse produced by disease of the aortic valves demonstrate the continuity of the blood stream from the left ventricle to the remotest arteries, but Harvey does not seem to have noticed the effects on the circulation of any alterations in the valves, or, indeed, any other than the normal condition of the valves. There is only one allusion to disease of the heart, and that an obscure one, in the "De Motu Cordis." Andreas Laurentius is mentioned as quoting the case of a man the left ventricle of whose heart was found post mortem to contain turbid, fœtid, acrid fluid. Laurentius thought that some turbid urine during the patient's life had therefore come from the heart. It seems possible that the disease of which fainting was a symptom may have been ulcerative endocarditis. Harvey evidently was rather incredulous about the observation.

Moses from Pisgah saw the good land which he longed to enter stretched before him, but was never to know its plains and hills, its deserts, its forests, and its towns. So Harvey, having seen clearly the course of the circulation and the precise normal action of the heart, was not permitted to see further into the land of truth he had obtained for mankind, nor was it till nearly a hundred years after he lectured to this College that a knowledge of valvular disease began to grow up.

The belief in the existence of polypus of the heart, about which so much was written in the eighteenth century, shows that the consequences of the doctrine of the circulation of the blood were not grasped for a long time. These polypi, which are very clearly described by Tulpius in 1641, with a beautiful drawing, and some twenty years later in Malpighi's "Dissertatio de Polypo Cordis," were clots sometimes ante-mortem, as in that which was removed from an aneurysm by Borelli, and sometimes post-mortem clots, as in those described as occurring in the right ventricle. Huxham in 1742 described to the Royal Society polypi in the hearts of two sailors in language which shows that he failed to grasp the impossibility of circulation with such obstructions:—

> [illegible] were shot a great way into the subclavian and carotid arteries but very little down the aorta.[2]

Matthew Baillie's demolition of the doctrine of polypi[3] may perhaps be regarded as the final step in the understanding of Harvey's discovery of the circulation:—

> Polypus consists of a mass of coagulable lymph, which fills up some [illegible]

Thus it took from 1628 to 1795 for Harvey's discovery to be thoroughly understood in the world of medicine. The above passage in Matthew Baillie's "Morbid Anatomy" may be regarded as the final preparation for the accumulation of knowledge on valvular disease. A few observations on disease of the valves may be found in earlier medical books, of which the best is perhaps that of Dr. James Douglas.[4]

> [illegible]

After describing an adherent pericardium and the normal right side of the heart, Douglas mentions the increase in size of the left ventricle and says:—

> The valvulæ called mitrales placed at the orifice of this ventricle are [illegible]

Everyone who reads this account will perceive how very near Douglas went to the discovery of the uses of auscultation. The loud noise which was to be heard proceeding from the cardiac region was probably a systolic murmur due to the rigidity of the aortic valves which was discovered post mortem. Huxham, in the paper which I have already quoted, says that in one of the sailors with polypi which he discovered post mortem, "I observed one of the semilunar valves of the aorta beginning to grow bony." There was, however, no real understanding of valvular disease till the time of Laennec and of his school.

I have maintained in my first lecture that endocarditis often producing permanent valvular disease is the central feature of rheumatic fever. What evidence is there of the extent in the heart of this endocarditis? Excluding cases of ulcerative endocarditis, the presence post mortem of disease of the mitral valve is the best obtainable anatomical evidence that the subject of the necropsy has had rheumatic fever. The mitral valve is rarely affected by chronic degenerative change or by syphilis. It may be affected by endocarditis and so deformed in the course of scarlet fever, of gonorrhœa, of influenza, of sepsis, or of pneumonia, but the number of cases due to these conditions taken together is small compared to the number due to the endocarditis of rheumatic fever. This endocarditis sometimes affects a large area of the interior of the heart. A woman, aged 19 years, whom I examined post mortem, was a good example of this. Her heart weighed 19 ounces and the pericardium was universally adherent. The endocardium of the right auricle was normal. The tricuspid orifice was wider than natural; the edge of the valve was greatly thickened and studded on its upper surface with numerous minute growths. One part only was free—a quarter of an inch at the anterior end of that part of the valve which is attached to the ventricular septum. At the root of the cords which proceed from the anterior part of the ventricular septum to the valve were numerous minute growths. The point of origin of this group of cords —they have no projecting musculi papillares—was thickened and these minute growths were on this thickened base and on the lower part of the cords. The other vertical cords showed no thickening, but there were some transverse thickened cords and a little roughness on the under surface of the valve. There was a small linear thickened patch in the right ventricle on the septum. Two of the pulmonary semilunar valves were adherent to one another and on each of these were numerous minute growths and one more prominent one. There were several much thickened patches of endocardium in the left auricle and there was a small rough patch on the auricular septum. The mitral orifice was somewhat dilated. The valve was fringed by a thick border of minute growths and all the tendinous cords were thickened. There was a general thickening of the aortic flap of the mitral valve. On the upper and anterior part of the ventricular septum in the left ventricle there was a thickened patch as large as a silver penny of Queen Victoria. The aortic valves were incompetent, each had numerous thickly-set small growths on the outer surface below the edges of the valves and with a connecting fringe of growths from valve to valve. In the hollows between the valves there were also minute growths. The valves were adherent to one another and were slightly everted. There were no signs of ulceration in the endocardium and no emboli in the viscera. This was an example of very widespread endocarditis. Taking 20 other cases (ten males and ten females) examined by me post mortem in which there was a probable history of rheumatic fever, as they came in my notebook, the following was the evidence of the area of endocardium affected :—

In none of the males were the signs of endocarditis confined to a single region, and in only two of the females was the mitral valve the only affected area. The first case shows how very widespread an endocarditis may be in rheumatic fever, and the others support the view that endocarditis tends to be widespread on the left side of the heart and sometimes extends to the right side.

Specimens of hearts are now gradually accumulating in museums in which naked-eye appearances resembling those of the endocarditis of rheumatic fever are proved to be due to various bacilli. Thus, in a male patient, aged 39 years (under the care of my colleague, Dr. J. A. Ormerod), who was ill for three months and whose necropsy I happened to witness, extensive recent endocarditis involving the mitral valve was found and gonococci were cultivated from the growths. The patient had died from endocarditis, which was a part of gonorrhœa. Here is the heart. There are large, soft, recent growths on the aortic valves with considerable destruction. In another heart showing endocarditis belonging to our collection at St. Bartholomew's Hospital, which I show you, a pneumococcus was cultivated from the growths, and in another the bacillus coli was found in abundance in the endocardium. The history of a few cases in my wards in which valvular disease due to an acute endocarditis was found and in which the only acute disease of the patient's past history was small-pox, added to the fact that pericarditis occurs in small-pox, makes it seem probable that an endocarditis may sometimes be due to the organism of variola. A passage in the Loimologia[5] of Dr. Nathaniel Hodges may, perhaps, point to what is in itself likely, the occurrence of endocarditis in plague :—

> I was sent for to a youth of about 14 years of age who had continued free of the infection, after his mother and the rest of the family had been visited by it, when all on a sudden he was seized with such a palpitation at heart that I and several others could hear it at some considerable distance, and it continued so to do till he died, which was soon after.

It was in the eager search for knowledge on this and other parts of the morbid anatomy of plague that my former clinical clerk, Dr. C. T. Raikes, lost his life in Singapore and I cannot allude to the post-mortem appearances of plague without commemorating the keen observation and intelligent devotion to the increase of knowledge of this young Oxonian.

The course of the following obscure case showed an unexpected occurrence of endocarditis and subsequent valvular disease.

> A boy, aged 10 years, was admitted to St. Bartholomew's Hospital with a rash on his face, legs, and arms, and ulcerated lips and some sore throat. The spots were pimples with bullæ in the centre and gradually faded away and the mouth healed. The throat gave a pure culture of streptococcus. A cultivation of his blood gave a growth in broth of yellow staphylococcus and some streptococci. The temperature was 100° for two days, and then became normal. On his admission, on March 8th, 1907, his heart sounds were normal and so continued till April 8th. Then a short presystolic murmur was audible just within, and a little below, the left nipple, and a well marked thrill was felt at the apex. On April 22nd the thrill [illegible] murmur was fainter. The rash was most [illegible] nature of the disease was obscure I aske[illegible] express their opinion on it. Dr. Ormerod, [illegible] J. H. Drysdale were of opinion that the co[illegible] and Dr. S. West suggested that the rash belonged to the class of bullous erythema. The murmur and thrill were present when the patient left the hospital, otherwise well, on April 26th.

There were no joint symptoms of any kind and no chorea followed the illness. It was probably an example of endocarditis and consequent valvular disease originating in some sepsis. I suspect that cases of what is called heart failure in influenza may sometimes be due not only to affection of the myocardium but to endocarditis which may sometimes interfere seriously with the action of the valves without causing a murmur. Dr. T. J. Horder has demonstrated the presence in the endocardium of the influenza bacillus. There are two specimens in the St. Bartholomew's museum. In lobar pneumonia it is not common to find clinical evidence of endocarditis, but there is no doubt that the pneumococcus is a cause of endocarditis. Here is a heart showing growths on the tendinous cords and edge of the mitral valve from which pneumococci were cultivated.

It is interesting to observe that in these cases as in those of *ulcerative endocarditis valvular disease, often the result* of long past endocarditis of rheumatic fever, *is* often present, as if an already damaged endocardium formed a favourable ground for the growth of streptococci and *other* organisms.

The view of 30 years ago was that endocarditis was an occasional complication of rheumatic fever. I have tried to show that endocarditis is its central feature. It is clear *that* endocarditis has many true species, some determined bacteriologically, some resting their specificity on clinical observation alone. *Fresh species will certainly be discovered.* The nature of the endocarditis of rheumatic fever seems at present to rest on clinical observations alone. It is none the less a good working species. Let us proceed to examine its effects upon the heart.

I may begin the subject by showing you these two specimens. This heart is that of a woman, aged 20 years, whose post-mortem examination I lately attended. It shows some old thickening of the cords and edges of the flaps of the mitral valve and on one flap a small raised red patch of recent endocarditis. Seeing that the uterus contained a fœtus I asked the demonstrator to open its heart and we saw a similar patch of recent endocarditis on the mitral valve of the fœtal heart. I have myself never heard a murmur which I could attribute to an alteration of the fœtal heart sounds and having once asked the late Dr. Matthews Duncan if he had he said that he had never heard any sound from which he could diagnosticate fœtal endocarditis. The heart I have shown you is the only one in which I have ever seen a true fœtal endocarditis in progress. It was clearly part of the maternal infection and it is interesting to observe that while congenital malformations described as due to fœtal endocarditis are generally on the right side of the heart in this case it was the mitral valve that was affected exactly as it was in the mother.

The tricuspid valve is found to show signs of endocarditis in a good many cases post mortem. Thus it was affected in nine out of the 20 cases mentioned above. I do not agree with those who maintain that tricuspid disease can be frequently discovered by auscultation. I incline to doubt any determination of it during life in which pulsation of the veins of the neck has not been clearly made out. And here I wish to point out the importance of teaching men as a matter of habit never to arrive at the diagnosis of any form of valvular disease from physical signs alone. Too great care cannot be given to the minute study of the physical signs in every heart, and to compare the observations of different days greatly assists to the complete knowledge of the valvular state. If the observer will write down precisely what he hears and on the next occasion do the same without looking at his former note he will learn whether what he hears is constant and if inconstant how it varies. But when the precise physical signs have been made out they must be considered in relation to the movements of the heart, to the character of the pulse, and to the general state of the patient before an opinion is expressed on the nature of the valvular disease. The most striking illustration of the importance of the pulse in relation to the interpretation of a murmur occurs when obstruction at the orifice of the pulmonary artery is the sole lesion. The loud systolic murmur audible is not always distinctly plainer at the second left intercostal space than at the right or on the sternum, and it is to be heard over a considerable area of the chest. It might easily be mistaken for an indication of obstruction at the aortic orifice but that the pulse is absolutely normal. When this is remembered the determination of obstruction at the pulmonary valves becomes one of the most certain among interpretations of cardiac murmurs. A minute search will show faint traces of affection of the right side of the heart due to rheumatic fever in a proportion of cases, but such are very rarely indeed to be found on the pulmonary valves, and still more rarely in sufficient size to cause a murmur. I have never met with an example of regurgitation at the pulmonary orifice. The clinical evidence of affection of the right heart in rheumatic fever is very small.

---

[5] Second edition, London, 1720.

The left side of the heart and particularly the mitral valve, or the mitral and aortic valves, and rarely the aortic valves alone, are the parts of the endocardium most often deeply affected in rheumatic fever, while the degenerative changes of later life and the effects of syphilis are more often seen in the aortic valves. We speak of mitral obstruction or stenosis and of mitral regurgitation. Since mitral regurgitation is often due to thickening and shortening of the tendinous cords, and since that condition is often associated with thickening of the edge of the valve and the projection of minute growths from it, it is clear that in many cases in which the chief effect is regurgitation some of the physical signs of obstruction may be present, while, on the other hand, extreme narrowing of the orifice by adhesion of the flaps of the valve to one another, though its physical signs are nearly the same as in the other case, has a different effect on the heart and on the circulation as a whole. The commonest physical signs of mitral obstruction are a thrill confined to the region of the apex beat and a presystolic murmur heard in the same region, and these are accompanied by an unequal pulse of diminished volume. The thrill is often systolic in time; sometimes presystolic or including both periods. It indicates some rigidity of the edge of the mitral valve and is never absent in that form of mitral obstruction which is due to the firm adhesion of the two flaps of the valve. A thrill may, however, be present without this adhesion, when there is a thickening of a part only of the edge of the valve or a rigid projecting growth upon its edge. If there is no localised thrill at the apex there is no mitral obstruction. If at the same time a murmur thought to be presystolic has been heard at the apex, further investigation must be made, and it will generally be discovered that it is in fact diastolic and is due to aortic regurgitation, even though it may for a time have been heard at the apex and not at the right base. Changes of position, raising of the arms, and the administration of nitrite of amyl will assist the observer.

Is a definite thrill at the apex ever due to any other cause than mitral obstruction in some form? The answer to this question is that such a thrill sometimes occurs when no other change is present but rigidity of one or more aortic valves. In some such cases the thrill may be felt more plainly still at the second right intercostal space, though definite at the apex. In others, though a thrill is only to be felt at the apex, it is certainly not due to the mitral valve and is due to the aortic valves. A constant thrill felt at the apex only is always present when the flaps of the mitral valve are adherent and thickened and also when a part of the edge of the valve is rigid or a rigid growth projects from it. When a patient has had a systolic murmur loudest at the apex and while the temperature is raised a thrill comes to be felt there which was not there before, it is often the case that adhesion of the mitral flaps has taken place and a permanent mitral stenosis been established. Such permanent stenosis, when it is the immediate issue of an attack of rheumatic fever, embarrasses the heart, but is unaccompanied by any hypertrophy of the left ventricle. Therefore, in a case of mitral stenosis, if there be well-marked hypertrophy of the left ventricle and no chronic interstitial nephritis, other valvular disease, or adherent pericardium, it may be assumed that the primary effect of the endocarditis was mitral regurgitation, that this was the cause of the hypertrophy, and that adhesion to one another of the flaps of the valve was a subsequent event. When mitral stenosis has been proved by repeated examination to be present, and provided there is no chronic interstitial nephritis and it is known that no different valvular lesion existed in the past, and the size of the heart, including the left ventricle, is increased, then, and perhaps then only, may the diagnosis of adherent pericardium be safely made.

Here the importance of examining the heart by means of electric light may be urged. It sometimes gives an exact notion of the nature of the enlargement present. The murmur of mitral stenosis is always the most confined in area of all cardiac murmurs. The murmur of mitral regurgitation is the most widely heard of cardiac murmurs. It is loudest at the apex and generally loud over the whole front of the chest and is audible in the left axilla and at the angle of the left scapula and often over the whole back, but when it is so it is always louder at the angle of the left scapula than at the right supraspinous fossa. Is this widespread area of sound present in every case of mitral regurgitation? To this question a negative answer must be given, for if the heart is acting feebly after a patient has been lying in bed for some weeks the murmur may be very faint and not audible in the axilla or at the angle of the scapula, while a week later, when he has been up and the muscular action of the heart is stronger, while the temperature chart shows that no further endocarditis has taken place, the murmur may easily be heard at the angle of the left scapula.

Here must be considered the question of systolic murmurs which are not associated with any history of endocarditis or with any rise of temperature and which disappear altogether: the murmurs of chlorosis and of anæmic states. These may be heard at the angle of the scapula when they are loud in front. They resemble the systolic murmur of mitral regurgitation, and I believe them to be due to a temporary mitral regurgitation due to the feebleness of parts of the cardiac wall, including the musculi papillares. This hypothesis accounts for their relation to chlorosis and seems to me to rest on a basis of observed fact which is not present to support the hæmic theories. Such murmurs should be regarded as indicating a temporary mitral regurgitation, and the œdema of the feet which occurs in those who have such murmurs as due to the valvular defect.

Is a systolic murmur loudest at the apex always a proof that a patient has mitral regurgitation? This cannot be asserted, for the systolic murmur of aortic obstruction is sometimes, though rarely, louder at the apex than at the base, and I have met with a few cases in which it was audible at the apex only. I cannot prove that this was due to a thickening of the cusp nearest the ascending part of the mitral valve, but if this were so it might explain the conduction to the apex. Such a murmur becomes faint beyond the apex and though loud there is not to be heard at the angle of the left scapula. Here, again, the character of the pulse must be taken with the auscultatory results.

It may be proper here to object to such phrases as "a mitral murmur was heard at the apex"; "an aortic murmur was heard on the sternum." By thus mixing the premiss [illegible] murmur the value [illegible] heard should be [illegible] that observation. The record of what was heard is an observation of scientific value only to be impugned by evidence of a defect of the sense of hearing in the observer. The clear statement of exactly what was heard, of the time of the murmur in the cardiac cycle, of the place where it was loudest, and of the area of the chest over which it was audible, enables future readers to accept or reject the conclusion drawn by the observer. The mixed statement leaves a conclusion which the future reader has no opportunity of considering, and his acceptance or rejection of it can depend on the authority only of the person making it.

The definite character of the pulse makes the determination of aortic valvular disease, whether obstructive or regurgitant or both, comparatively free from difficulty. The murmurs are the loudest of all valvular murmurs when loud, though they are occasionally barely to be heard. Aortic murmurs may sometimes be heard without touching the chest wall. I have once at St. Bartholomew's Hospital heard a murmur not indeed so loud as that described by Douglas which I mentioned in my last lecture but loud enough to be heard as one stood near the patient without stooping. It was systolic and was due to aortic obstruction. I have since heard murmurs in three cases, all of aortic valvular disease, which were audible without touching the chest.

A woman, aged 50 years, complained of pain in her left shoulder and down her left arm occurring in paroxysms. These had increased for six years in frequency and when they came on she felt stifled and could not move. I myself saw her in one of these paroxysms, and there could be no doubt that it was an attack of angina pectoris. The impulse of her heart was always greatly increased and the apex beat was in the sixth left intercostal space an inch outside the nipple line. A diastolic thrill was to be felt over the sternum at the level of the second intercostal space. A very loud diastolic murmur was audible in the second right intercostal space, down the sternum, at the apex, at the angle of the left scapula, and in the right supra-spinous fossa. The murmur was loudest at the second right intercostal space and was preceded by a very faint systolic murmur. The pulse at the wrist was of the kind often compared to a water hammer. The diastolic murmur was distinctly audible three measured inches from the patient's sternum without stethoscope and without touching the chest or any part of the body. She was admitted to St. Bartholomew's Hospital a month later and the murmur continued to be audible without contact for a week. Then it became less loud and the anginal attacks less frequent, and it was no longer audible without a stethoscope though it always remained audible with one.

A labourer, aged 41 years, who had shortness of breath and palpita-
pectoris. The impulse of his heart was
it was three-quarters of an inch outside
left intercostal space. A double thrill,
be felt all over the cardiac area. At the
a loud systolic and equally loud diastolic
st there but audible down the sternum,
at the apex, at the angle of the left scapula, and at the right supra-spinous fossa. The pulse at the wrist was very sudden. Both these murmurs were audible without touching the chest at a distance of three measured inches from it. After rest in bed for 14 days the murmurs could no longer be heard without touching though plain with a stethoscope.

A man, aged 22 years, had a much increased cardiac impulse. His apex beat was in the sixth left intercostal space just outside the nipple line. A very loud diastolic murmur was to be heard at the base, audible all down the sternum, and this was easily heard without touching at one inch and a quarter from the chest wall.

The murmur of aortic valvular obstruction and that of regurgitation are sometimes very faint or only audible now and then. If the patient be made to raise his arms above his head a faint murmur often immediately becomes distinct and the same effect may sometimes be produced by the inhalation of nitrite of amyl, but the former method is the better. The murmur of aortic obstruction may often be heard at the right supraspinous fossa, and this is a useful physical sign, for if a systolic murmur be heard in the right supraspinous fossa and nowhere else on the back it is a very certain sign of aortic obstruction, a fact which has not been generally observed and is not mentioned in books on auscultation, not even in the book which we have all read with enjoyment, in which Dr. S. J. Gee has in such measured and well-chosen language set forth one of the best arranged statements of knowledge on auscultation and percussion in English. The diastolic murmur of aortic regurgitation may also sometimes, but much less often, be heard in the right supraspinous fossa.

In a complicated case of valvular disease, when it is wished to arrive at an exact conclusion as to the valves affected, it is often a good plan to listen first at the back and hear what can be heard there without prejudicing the mind by listening first to the louder sounds in front.

The murmur of mitral regurgitation is often very loud at the angle of the left scapula; the murmur of aortic obstruction is sometimes very distinct in the right supraspinous fossa. The murmur of mitral regurgitation, it is true, is often very loud over the whole back, sometimes even including both supraspinous fossæ, but this is not always so, and in a fair proportion of cases it will be possible to distinguish the areas of the two murmurs. The murmur of aortic obstruction will rapidly become fainter as the stethoscope is moved obliquely downwards towards the dorsal vertebræ, and the murmur of mitral regurgitation will be made out to be louder near the angle of the left scapula than near the dorsal vertebræ or beyond them to the right. It may be audible up to the right supraspinous fossa, but when that is reached an immediate increase in the volume of sound is perceptible, for two murmurs each produced in the systole are heard together. A good many systolic murmurs of aortic obstruction are not audible in the right supraspinous fossa while nearly all murmurs of mitral regurgitation are audible at the angle of the scapula. In cases where both murmurs are audible behind I have proved this method of distinction by repeated observations and recommend it to the College.

A character of murmurs produced by aortic disease, when heard in the front of the chest, is their apparent nearness to the end of the stethoscope. This is often of great assistance in distinguishing each murmur when those of mitral regurgitation and of aortic obstruction are both present.

A single observation will never enable one to dogmatise about a complication of murmurs and however erroneous the opinion of some other man may appear to a listener to a heart it is wise not to say this or that cannot be heard till repeated examination has been made. Murmurs, indistinct or inaudible, often become plain as the action of the heart alters.

It is often very difficult to explain the alterations of murmurs. An adherent pericardium, not, I think, by its thickness but owing to its interference with the muscular rhythm of the heart, may produce confusion as to the valves affected. I hope this discussion of a few parts of the subjec of valvular murmurs is not too trite for the College. Ther seems to me to be so much that is difficult in the subject o valvular disease that I have ventured to discuss not th whole of it but a series of parts in which I chance to hav had good opportunities of observation.

The first attempt in England to explain the pathology o rheumatism was that of Dr. Clopton Havers of St. Catharine' College, Cambridge, in his "Osteologia Nova," published i 1691. Few have read the book, yet its account of th structure of bone has secured for its author the mention o his name with the Haversian canals by every student o medicine since his time. He advanced the view tha rheumatism was due to a sort of jelly "concreted upon th superficies of the muscles." He mentions in support of th hypothesis that rheumatism was due to this mucilage o jelly a case of a curious tumour of the leg, perhaps hydatid, since it contained "many smaller pieces of whit curd mixed with a serum," which he thought showed tha mucilaginous glands existed in the muscles and becam diseased, and that they were the source of the outpourin which constituted rheumatism. Since the time of Haver many pathological hypotheses have arisen on the causation o rheumatism. None of those relating to rheumatic fever nee be recapitulated. Its resemblance to diseases produced b definite organisms is too close for any other hypothesis o origin to be at present probable. It might obviously b included among what Sydenham would have called th epidemic diseases of the year. The pain which it produce we know how to relieve, but when it is considered that it i the origin of most of the valvular disease of the first half o life and of some proportion of the valvular disease of th second half of life, and through them of all the distresses o slow death by dropsy and instant death by affection of th muscular tissue of the heart, as well as of all the diminutio of working power which is a necessary result of valvula disease long before it has begun to threaten life, w anxiously look to the bacteriologists for a conclusive demon stration of the nature of the organism which produces it an of its natural history as an important aid to the preventio of rheumatic fever and the diminution of its incidence o the population and of its long train of disastrous cons quences.

The Irish Association.—The annual banque of the Irish Association in London, Dr. H. Macnaughto Jones, the President, being in the chair, will take place a King's Hall Rooms, Holborn Restaurant, W.C., on Thursday May 27th, at 7.30 p.m. Field-Marshal Earl Roberts an Admiral Lord Charles Beresford will be the principal guest of the evening.

A Clinical Lecture

ON

THE REMOVAL OF TUMOURS OF THE LARGE INTESTINE.

Delivered at University College Hospital, London, on Jan. 27th, 1909,

BY ARTHUR E. J. BARKER,
F.R.C.S. ENG. & IREL.,
SURGEON TO THE UNIVERSITY COLLEGE HOSPITAL AND CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK, S.W.

GENTLEMEN,—It may fairly be said now that every part of the large intestine from the cæcum to the anus is accessible to surgical operations for the removal of tumours of various kinds with or without obstruction. Comparatively recently we have had before us several cases illustrating this branch of surgery and these will form the basis of our clinical lecture to-day.

The tumours with which we have to contend in the large intestine are almost invariably columnar epitheliomata of varying degrees of malignancy. But, as a rule, they are slow growing and have but a moderate tendency to invade the lymphatic glands or generalise in other parts of the system. They may be regarded, then, as offering generally a good prospect of thorough removal under favourable conditions. In addition to these tumours, we also meet with tubercular infiltration of the walls of the bowel forming masses which obstruct its lumen, with actinomycosis and with intussusceptions. Excluding the latter, of which I have already spoken in another clinical lecture, and the actinomycotic masses which are rare and have not come into my own experience in the large bowel, we will consider some of the cases of malignant and tubercular tumours which have come under our notice lately.

The whole question whether we can safely remove such masses is influenced more by the presence or absence of associated obstruction than by anything else. If there is but little or no obstruction to the passage of fæces through the affected part the removal of a segment of the bowel is to a large extent merely a question of skill and accuracy of technique. But if obstruction is present great judgment is necessary as to whether we shall first relieve the overloaded gut by making an artificial anus for a few weeks' preliminary drainage, or at once proceed to remove the tumour and unite the divided ends. As a general rule, the first course is the best. There are several reasons for this. In the first place, the technical difficulty of dealing with a bowel greatly distended with fæces above a constriction are very great. Not only is it very hard to remove the tumour without soiling the peritoneum and abdominal wound, but it is in some cases almost impossible to adapt and suture the distended proximal end to the more or less contracted distal end when the tumour has been excised. This can in some cases be avoided by lateral anastomosis with closure of the ends, but unless the mesocolon is long or has been mobilised by division of its mesentery it may be very hard to bring the parts side to side. But even though this may be accomplished and the side-to-side junction of the colon be made, there is another risk from immediate anastomosis of a loaded gut without a preliminary drainage which must never be forgotten. [illegible] ler the strain [illegible] condly, some days after the junction has been effected by the cutting out of the stitches in the proximal part. You may ask why this cutting out may occur so late as perhaps the fifth day when union of the divided viscera should be as sound as it is at such a time after a gastro-enterostomy, for instance; but it is easily understood by those who have seen many of these cases. The part of a bowel proximal to any bad obstruction becomes in course of time paralysed and sodden with the toxins of fermenting fæces. Its tissues under these conditions will not hold firmly and there is an absence of that healthy plastic peritonitis around them upon which the ultimate soldering up of the two ends of the bowel depends The result is a giving way of the stitches at one or more points always in the proximal end and either a perforation leading to death or a fæcal fistula on the surface of the abdomen. The difficulty of determining by the eye or by touch whether bowel above an obstruction is sound enough for suture is so great that it is a better and safer rule to make a provisional drain opening in it and allow the gut to recover in the course of a couple of weeks or so before attempting a junction. This may or may not be combined with the removal of the tumour according to circumstances. This does not apply to obstruction of the small bowel where enough can be drawn out to reach a part above where the coats are sound. Here we have only to draw the coil downwards for several feet, clamp it, and remove the sodden loaded part with its contents and make our junction between healthy tissue below the point of obstruction and healthy tissue high up, as I did in these cases from which these pieces of black semi-gangrenous gut several feet long were successfully removed (specimens shown). Such an extensive removal of a loaded colon cannot, of course, be done. Moreover, it is a well-known fact that where there is a stubborn obstruction low down in the colon which has persisted for a long time a state of ulceration frequently exists in or about the cæcum, and this would prevent any sound junction, even if it were possible to unite the cæcum with the lower part of the large intestine after removal of the intervening portion. It is better, then, I repeat, to drain an obstructed colon for a long enough time for it to recover its muscular tone and expel all fermenting fæces and their toxins before attempting any junction after excision. This will usually take from two to three weeks. But in those cases of tumour of the large intestine where obstruction does *not* exist to any large extent, or where the fæces are solid, the bowel is sound enough for all the purposes of repair and successful excision of parts of it depends on manipulative skill and accurate technique. A careful study of the history and course of every case and a close examination of the abdomen should precede any operative undertaking especially to determine whether the bowel is likely from the history to be loaded with liquid fæces or can be shown by palpation to be so. The practice of administering drastic purgatives in cases of obstruction low down is responsible for many of the unfavourable conditions due to loading of the bowel with liquid fæces which we meet with in these cases. Enemata, on the other hand, are always desirable and should be repeated over and over again if time permits But not just before the operation. It is better to have the distal part of the gut in a state of rest at the time of operation, empty or not.

Perhaps the best way of bringing under your notice the technique of removal of the cæcum for tumour without obstruction is to describe what was done for a patient who has recently left the hospital well from whom the specimen before you was removed.

The patient, aged 40 years, was admitted to University College Hospital for a tumour in the right iliac fossa of about the size of the two fists and a fæcal fistula leading into it. She had been operated on in the provinces two years before for fæcal abscess supposed then to be due to a tubercular appendix. Since then the operation wound over the cæcum had never quite closed and fæces continued to be discharged from a fistula leading deep into the swelling. She was on admission much emaciated and anæmic but apart from what has been mentioned there was nothing to be found in the abdomen. The diagnosis we made was tubercle of the cæcum. As there was no prospect of closing the fistula by any other means it was determined to excise the tuberculous cæcum This involved a very extensive operation under unfavourable conditions as to asepsis in view of the fæcal fistula but favourable inasmuch as there was no obstruction. After every possible process of cleansing had been carried out for several days two elliptical incisions meeting at both ends were made, including the old scar with the fistula in its middle. These incisions were deepened until a clamp could be applied to close the fistula so as to prevent any escape of fæces during the rest of the operation. When by carrying these incisions deeper the abdomen was opened it was found that the whole cæcum and part of the ascending colon were converted into a large solid mass of tubercular scar tissue imbedded in adhesions in the omentum and parietal peritoneum. It was also seen that the last part of the ileum for about two feet and the whole of the ascending colon were studded closely with large countless tubercles which also appeared in smaller amount on other coils which were seen in the wound [specimen shown] It was plain then that the whole cæcum, ascending colon, and a couple of feet of ileum would have to be excised to give any good prospect of a riddance of the disease. This was accomplished by double clamping of the ileum in *relatively* sound tissue where only a few tubercles could be seen and dividing it between the clamps. The proximal end of the ileum was then implanted into the transverse colon. The last two feet of the small gut, the cæcum, and the ascending colon were then separated from their attachments, their vessels being carefully tied off, and the colon was double clamped on the proximal side of the ileo-colic anastomosis, divided between the clamps, and its distal end sutured by two rows of stitches, the last being sero-muscular, the first through all coats. All this was done with the greatest care as to asepsis, the large pelvic dissection being packed with gauze as it was proceeded with. When the gauze was removed at the end the cavity was dry. But as we had been working on a part with a fæcal fistula in it and seeing that it might have been infected during the operation, I felt that the extensive wound ought to be drained. This was done with a large apron of gauze stuffed with a long strip of iodoform gauze. The ends of the wound were sewn together. The operation, which lasted nearly two hours, was done under spinal analgesia, which gave ideal conditions for both the operator and the patient, who had begged for it in preference to general anæsthesia, of which she had most unpleasant experiences. Just at the end the patient began to feel a little but made light of it. There was no shock and the large cavity contracted slowly until only a track was left. This seemed to be kept from healing either by a deep ligature or a tubercular nodule. When the patient left hospital for the country she was putting on weight and had only a very trifling sinus yielding a drachm or two of thin discharge daily.

The specimen now before you shows the most extensive tubercular disease of the parts involved, and where the cæcum is laid open it is seen to be shrunken and stenosed, so that the passage through it would only have admitted a No. 12 catheter into the colon. Six damson stones were found in it, one of which blocked the contracted part. The bowels after the operation were soon regular and the motions normal until the patient went home.

This excision is typical of what can be done on the large intestine on the right side of the abdomen, whether for non-malignant or malignant disease. In either case I have come to regard it as perhaps the least difficult part of the colon to attack and most likely to give good immediate and remote results. My first excision for cancer of the cæcum done in 1899 was on the same lines and did well. For six years the patient was in the best of health but then presented himself with secondary deposits and died not long after. But six years of the best of health was gained. In this case the ileo-colostomy had to be done for acute obstruction, the excision following some five weeks later, and this obstruction was the chief risk in the case as already explained owing to the possibly unsound condition of the bowel above the tumour due to the putrid fæces retained there. As the event showed, it was sound enough to hold the sutures. But as a general rule it is better to assume that it is not safe to make an immediate junction, and therefore an artificial anus is made higher up in less damaged bowel unless a large stretch of the intestine can be at once excised with its contained putrid contents. The operation of removal of the cæcum is, of course, a severe one, and in the aged or very asthenic younger adults it will often be better to content oneself in the first place with simply anastomosing the ileum to the transverse colon. Later, if the general condition be much improved, the excision may be undertaken if the patient be in favour of it after the condition of things be fully explained. Some patients will face any risk in preference to having the prospect of inevitable slow death from cancer. It is here that much judgment and experience are needed; no hard-and-fast rule can be laid down. The immediate results, it has been said, of excision of the cæcum are good, and I believe it is correct to say that all the cases which I have contributed to the hospital records have recovered.

In the case of tumour of the transverse colon or splenic flexure a great deal depends upon whether there is much obstruction or not. If this is obviously present, as is often found, or in cases in which we are in doubt upon the it is a good rule to make an incision below the umbilic the middle line. It will then be seen whether small intestine is much loaded and distended. this is the case a coil from the lowest pa the ileum which can be reached should be drawn out o incision and held over a basin, the wound being packed gauze. The bowel is then opened with a knife or sc transversely and as much as possible of its content allowed to drain away. The more that escapes the b and it will now be possible in doubtful cases to pa hand into the abdomen and ascertain the exact seat and connexions of the tumour. Nothing in the sha excision should now be done, but as soon as the bow been well emptied the opening in it should be fixed wound as securely as possible and the latter clos round it with or without a tube in the orifice. If of the contents have flowed away with great relief sometimes better to close the opening by temporary st securing the sutured spot in the abdominal wound. after a couple of days, during which adhesions have f round the sutured knuckle, the stitches in the can be cut and further drainage of the intestine b provided for with less risk of infection of the men than if the fæcal fistula had been form once. Subsequently, when the abdomen has unl itself and the effects of toxic absorption have pass usually in four or five weeks, the tumour of the tran colon or splenic flexure may be excised in the first c a median incision above the umbilicus and in the sec an oblique incision from about the end of the tenth rib wards and forwards. In one of the most interesting, b worst, cases of obstruction I have ever had this was d Jan. 27th, 1904, with the best results, and the man i before you quite well, exactly five years later, t Jan. 27th, 1909.

The patient, a man over 57 years, was enormously dis and very ill and we could only infer from the sympton the tumour was in the splenic flexure. An opening wa in the small intestine two feet from the ileo-cæcal valve evacuated an enormous quantity of liquid fæces an This enabled the hand to be passed in and the colic noma was found at the splenic flexure. Some week the ileum proximal to the fistula was laterally anasto to the sigmoid flexure below the growth through an o incision in the loin. A few weeks after this the g was excised by opening up the last incision an colon above and below it was closed. Later the above the fistula and below the anastomosis was to direct all the fæces into the sigmoid and the part was left in the wound as a safety valve f colon which you remember was closed above whe growth was taken away. I heard of the patient in health a few weeks ago and have asked him to come examination to-day. You see him now strong and having put on several stones weight in the five years elapsed since the operation. To have attempted imm excision and end-to-end junction in this case in un bowel distended by putrid fæces would have been to disaster, and the same might be said of a short circui at once between the ileum and colon. It was thus nec to operate four times on him before the intestinal was rearranged. But it is otherwise in those cases of t of the transverse colon or splenic flexure in which ther distension and but little obstruction or only interm blocking. Here the resection and end-to-end or lateral tion can be done with a good hope of success. The firs in which I did this on the transverse colon some yea was in a woman, aged about 50 years, who had, it n mentioned, 6 per cent. of sugar in her urine. The grow removed from the transverse colon and she made a recovery. She came into one of the medical wards of th pital for hemiplegia, apparently of cerebral origin, s years later, some hemiplegia remaining, I believe, whe left. Here there was no previous drainage of the inte there being no distension, and the fæces abov seat of operation were solid formed scybala an intestinal walls were sound. But the thin walls colon were very difficult to suture accurately end to en I was not surprised to have to deal with a small fistula in the wound for a week or two, which, ho closed of itself without special treatment. It may be

Why not make a fæcal fistula above the growth *in the colon itself* in cases where it is very much loaded with liquid fæces instead of in the ileum as in the case recorded above and so empty all the colon direct? This may be done, but it is far more difficult to draw the distended colon out of the wound and make a safe union between its thin coats and the abdominal wall than it is to secure the thick-walled small intestine. Moreover, at the subsequent excision of the growth the presence of a fistula in the colon not far from the field of operation not only makes it more difficult to keep the procedure aseptic, but the attachment of the colon at the seat of the fistula makes the manipulation of the bowel far from easy. Again, it appears probable in these cases of obstruction of the colon in its transverse and splenic portions that liquid fæces can be emptied by anti-peristalsis through the ileo-cæcal valve and a fistula in the lowest part of the ileum.

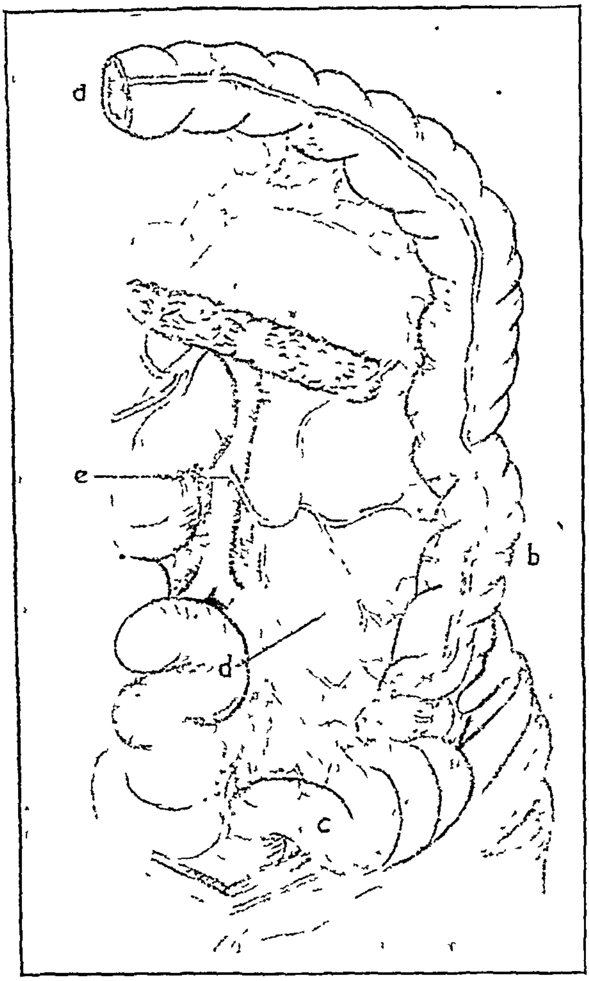
But in cases of sigmoid flexure tumour with distension with liquid fæces an artificial anus may be made in the transverse *colon or cæcum with advantage, and when the gut has* been unloaded for a few weeks the growth may be removed through a fresh oblique incision in the left inguinal region or just above it, and an end-to-end junction made. At a subsequent operation the artificial anus can be closed. But in some cases a better means may be adopted. This consists in operating at once over the sigmoid, separating the mesentery of the part in which the growth is seated, and drawing it out of the abdomen. Then when the wound has been securely stitched round both the proximal and distal portions the growth can be cut away and the upper part of the colon be drained with a Paul's tube for two or three weeks until the bowel above is healthy and sound. Then a second operation is done to unite the proximal and distal ends by opening up the old wound, including it between two curved incisions to secure fresh aseptic surfaces. This is a difficult operation from the point of view of asepsis, but it can be done successfully with due care. This was the course which I followed with perfect success just a year ago in the case of a patient in one of the southern counties who was suffering from carcinoma of the sigmoid with enormous distension of the colon. I heard from this patient himself, now perfectly well, a few weeks ago on the anniversary of the operation. This will be, as a rule, the best course in an average case of tumour of the sigmoid with much distension of the colon above, but in some cases where we feel sure from the history, from the recent passage of fæces and flatus, and from the appearance of the colon when exposed that the bowel above is not over-distended and is sound, we may at once proceed to resect the growth and unite the ends. This, of course, avoids the artificial anus with all its discomfort and the risk of sepsis immediately and at a subsequent operation, but there is always the possibility of being deceived as to the soundness of the bowel and we may have one or two stitches giving way and a fæcal fistula resulting. This, as a rule, will close soon, but there is, of course, a risk until it does so. I have treated several such cases in this way with good results, but in some a fæcal fistula has for a time given rise to anxiety. This is notably the case in a private case operated on some weeks ago still under my care. I thought that the history and the appearance of the bowel above the sigmoid growth pointed to sound and only slightly distended bowel and removed the growth through the left inguinal incision, making an end-to-end junction. But from the moment the gut was replaced in the abdomen and for days after there was a copious flow from the anus of liquid and very foul fæces. About the fifth day there was a little escape of gas when the drain-gauze was removed, and this was followed a day later by a little fæces and then more each day from the wound. But now the bowels are acting freely by the anus and the fistula is yielding very little. This case was complicated by a cystic ovarian tumour of the size of a large cocoanut, which nearly filled the pelvis, and by very bad piles, both of which made the emptying of the bowel below the juncture very difficult, and this may have thrown an extra strain on the sutures at the junction to which they yielded. But as the piles are better now and the rectum is emptying itself freely, the sinus in the original wound will probably soon close. The lady is otherwise quite well.

And now we turn to those tumours of the large bowel which are seated below the promontory of the sacrum too low for excision and union of the severed ends from an abdominal wound and too high to be reached with ease from below. These cases have always been a crux to surgeons in spite of the introduction of Kraske's operation from behind. Now, of course, where they are seated low enough to be reached by the dorsal or perineal methods and are not too widespread, they are dealt with by these methods. And it is surprising how much of the bowel may be excised from below. But there are many cases in which the growth lies in that part of the colon just below the promontory of the sacrum, where the mesentery is short, which are most difficult to reach from below, and the condition of whose mesenteric attachment as to infected glands cannot be ascertained from here. Moreover, if this portion be mobilised from below and pulled down the strain on its vessels is often so great as to arrest the current in them and the part is deprived of its blood-supply and dies. To meet the requirements of such cases a very bold but well-thought-out method has been proposed and practised within the last few years which, if severe and prolonged, has yet much to recommend it. *This is to attack the* tumour both from above through the abdomen and below from behind below the sacrum. But for this procedure to be carried out with success several conditions have to be present. The patients must be in fair general condition and not in an exhausted state, as unfortunately is so often the case before the condition is recognised and they are placed in the surgeon's hands, and they must be free of secondary deposits. Again, they must not be too stout, as it has been found that in obese patients the difficulties of technique are very great. Further, the bowel above the tumour must not be distended and loaded with fluid fæces. If it be so in any case relief must be first procured either by frequent enemata or by the formation of an artificial anus, preferably in the transverse colon, so as to place it as far away from the future opening in the abdominal wall for the excision as possible. Finally, such a procedure can only be successful in the hands of a surgeon who is fully aware of the anatomical facts on which the provision for the vascular supply of the long tract of bowel to be mobilised depends. For it is clear that if the lower end of the sigmoid flexure—i.e., the part above the growth—is to be brought down near or to the anus it will be necessary to separate the meso-sigmoid, as it is sometimes called, and also at least the lower part of the descending meso-colon. And if this be so, the vessels supplying these parts of the bowel must be carefully preserved, otherwise they will subsequently become gangrenous.

Let us glance at the arrangement of the vascular supply of the implicated bowel and see if it may be mobilised without the risk of cutting off the blood supply. You will remember that the rectum are supplied mesenteric artery. (Fig. 1e.) The left colic branch from this artery anastomoses above with the middle colic and below with branches of the arteria sigmoidea from the inferior mesenteric. The sigmoid artery, on the other hand, anastomoses below with the branches of the superior hæmorrhoidal artery, which may be described as the lowest terminal branch of the inferior mes-

meet the system of the inferior hæmorrhoidal plexus derived from the pudic artery. Now it is quite plain that if the bowel from the promontory of the sacrum to near the anus is going to be removed, the sigmoid flexure must take its place and its vascular supply must be uninjured when it is drawn down to the anus, and this without undue strain being put upon it. But it is equally obvious that the sigmoid and superior hæmorrhoidal arteries must be cut and tied if the sigmoid is to be mobilised. How, then, is the circulation in the sigmoid to be carried on if the sigmoid artery is tied off when its mesentery is *separated from the pelvic wall?* This is easy to understand if you will look at the arrangement of the vessels of the left colon. I show you this as given in Quain's "Anatomy." You will see that each of the arteries named just now as it approaches the bowel breaks up into numerous large branches forming a wide-meshed network all along the mesenteric attachment of the bowel from the splenic flexure to the rectum. This network is at least one and a half inches deep measured from the bowel. If, therefore, the sigmoid and superior hæmorrhoidal arteries be carefully tied about two inches from the bowel the large vessels derived from them receive their blood from the anastomoses with the left colic artery and supply the lower parts of the gut as before. But it is a *sine quâ non* that the ligatures on these vessels shall not be placed on them nearer than one and a half inches, and that the network between them and the bowel be preserved from all injury and be not overstretched. You will best realise how such an operation is carried out if I describe to you a case lately in my wards which some of you have seen quite convalescent.

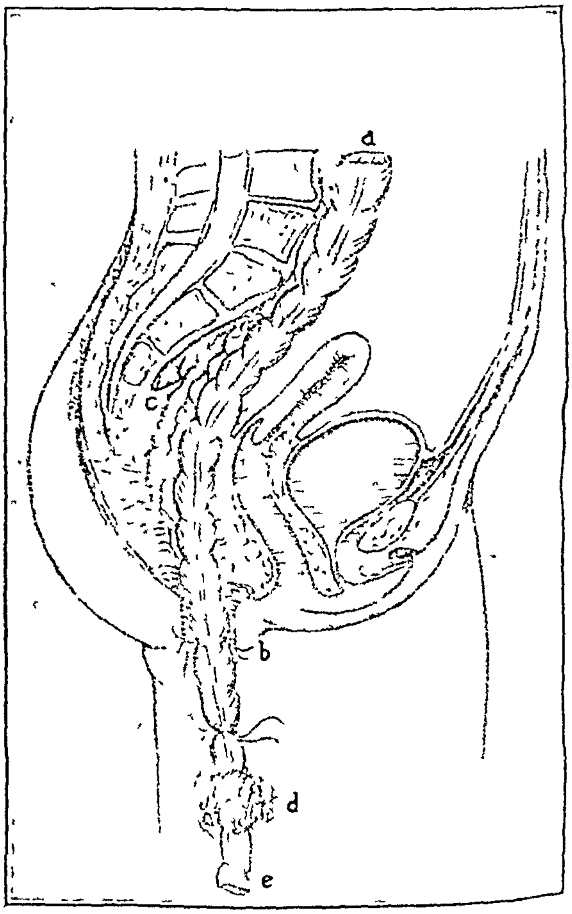
FIG 1.



a, Transverse colon. b, Descending colon. c, Sigmoid flexure. d, Line of division of sigmoid and superior hæmorrhoidal arteries e, Inferior mesenteric artery. (After "Quain's Anatomy.")

The patient was a slightly-built thin woman, aged 40 years, with symptoms of intermittent obstruction with the passage of blood and mucus. There was no distension and no tumour could at first be made out either by rectal or abdominal examination. But by the use of the proctoscope we eventually saw clearly a carcinomatous ulcer high up. No glands or secondary deposits could be made out and the uterus and vagina appeared normal. You will see from this that the case fulfilled several of the conditions mentioned above, and was so far favourable for operation. Having cleared out the bowel by laxatives and enemata and cleansed the abdominal wall and sacral region rigorously, the operation was begun with the patient lying on her back. An oblique incision was carried from about one inch above and internal to the spine of the ilium to nearly the middle line an inch above the symphysis pubis. Through this skin incision the fibres of the three muscles were separated to nearly the same extent. Where they ran into the sheath of the rectus the latter was opened enough to permit of this muscle being drawn inwards with hooks. The peritoneum was now slit up in the line of the main wound and the sigmoid presented. It was then seen that it ran into a mass of carcinoma occupying the pelvic colon at the level of the promontory too low down for removal and anastomosis of the divided ends from our abdominal opening. At the same time it seemed otherwise a favourable case for excision, for there were no glands or secondary deposits or adhesions to be made out. It was therefore determined to remove it by the combined abdomino dorsal method. To this end the sigmoid was first drawn out and the abdomen about its root was well packed with a long roller of gauze. Then the meso sigmoid was detached from the pelvic wall at least one and a half inches from the border, having first been transfixed with double threads between which its vessels were divided. This separation of the mesentery was carried upwards until the lower part of the descending colon was likewise free and downwards until the upper part of the rectum was mobilised from the hollow of the sacrum. The gauze was then drawn out, the wound revised, and the abdominal opening provisionally closed by a few stitches and carefully dressed *pro tem*. The patient was then turned over to her left side and an incision curving from the left side of the sacrum to the middle line and down to about two inches from the anus was made down to the bone. The coccyx was removed through this opening with as little disturbance of surrounding structures as possible

FIG. 2



a, Last part of descending colon. b, Last part of sigmoid sutured to everted anal portion of rectum c, Peritoneum sutured to sigmoid after the latter is drawn down d, Growth drawn out through anal portion. e, Rectum below the growth

The rectum was now pulled downwards until the openings in the peritoneum on either side of it made from above could be seen. These openings were then continued downwards on either side of it as far as the peritoneum extended. The whole of the large bowel from the last part of the descending colon to above the anal portion of the rectum was by this time mobilised and the sigmoid loop was converted into a straight tube of which the part well above the growth would easily reach the anus. The anus was now stretched by an assistant who took no further part in the operation. Then a bulbed rod was passed through the anus and up to the growth and from the dorsal wound a stout cord was tied round the whole bowel below the bulb. The rod being now withdrawn brought the growth (with some help from the hand above) within and through the anal portion like an intussusception and turned the anal portion inside out. (Fig. 2.) The anal portion was now divided all round about two and a half inches from the skin margin exposing the lower part of the pelvic colon about four and a half inches above the growth. The cut edges of the anal portion were now united to this by stitches passing through all its coats and the sero-muscular coats of the colon within. Then a stout thread was tied round the whole protruding colon about two inches below the line of suture and the bowel was cut across below this and well above the growth. All this was done without opening the bowel until the edge of the everted anal portion was stitched to the inner tube, and this was done cleanly so that any possible soiling of the abdominal or sacral wounds was avoided. The thread round the gut below the line of suture prevented the escape of fæces or mucus for a couple of days during which union would be pretty firm. After this we revised the abdominal wound and pelvis and found both satisfactory and stitched up our abdominal incision in layers. Then the dorsal wound was in part closed and drained with gauze. The part of the colon below the line of suture was left to slough off, which it did in a week, and the bowels began to act at this time. The abdominal wound healed without a flaw under the first dressing and the dorsal contracted up and closed without incident. The patient showed no trace of abdominal trouble from beginning to end, and left the hospital with full control over her motions. The patient presented herself for examination in the middle of April in excellent condition and with perfect control over fæces and flatus. This was due to the fact that beyond being turned inside out *pro tem.* no injury had been done to the anal portion of the rectum which contains the sphincter apparatus.

This intussuscepting method when it can be accomplished with moderate-sized tumours renders it possible to do all the stitching part of the operation outside the anus, whether it unites the colon to the everted anal portion or actually to the margin of the anus after removal of the mucous membrane.

This so-called "combined" procedure is beyond doubt a severe one and not suited for decrepit or obese people. In this case there was little shock and all the objects we had in view were carried out.

Now we come to the case of growths of the rectum within reach of the finger in the anus. These can undoubtedly be mobilised by the dorsal wound alone, and in many cases at all events the upper part of the bowel can be brought down far enough for junction with the intact anal portion, if not with the anus itself. But the dorsal method alone has its weak points. The chief of these is that possible infection of glands high up cannot be ascertained, nor can the condition of the peritoneum. And even if it is recognised that these structures are more or less the seat of secondary deposits these cannot be removed so cleanly as they should be. Again, the arrest of bleeding from the dorsal wound is in some cases as difficult as it is indispensable; and further, when after mobilisation of the gut from below the parts are drawn down, there is always the possibility of too much strain being put upon the vessels of the intestine and of sloughing being caused thereby. For the loops of vessels formed by the superior hæmorrhoidal artery are by no
the
the
ised
be
no alternative but to make a sacral anus with all its disagreeable results as to incontinence of fæces. These defects in the dorsal method have certainly justified a search for some procedure which shall eliminate them even at greater risk to the patient. So serious a condition as cancer of the rectum justifies the running of great risks if we have a prospect of ridding the patient of an otherwise inevitably fatal disease. And in theory, at all events, the combined abdomino-dorsal method does offer such a prospect, and not only that but of doing so without forfeiting the sphincter action of the anal portion of the rectum. Nevertheless, there are still strong opponents of the combined method, and that among surgeons who have a very large experience running into hundreds of operations in this class of cases. And for a long time to come it seems likely that the sacral procedure will hold the field for ordinary cases. But still, it is a significant fact that Kraske, who originated the dorsal method and who has done more to popularise it than any living surgeon, has lately come forward with a plea for the abdomino-dorsal method as a measure which gets over many of the defects of his own original operation. Of this latter I should like to speak more in detail and to give you some of my own experiences, but time fails. I should like, however, to add one word as to the present risks of the two methods. The mortality of Kraske's operation in the hands of some skilled surgeons who have performed it hundreds of times has fallen from 32 per cent. to below 10 per cent. The abdomino-dorsal method has not been practised long, and we have very few statistics to guide us so far. But in Kraske's own series of ten cases reported in April, 1906, he had 40 per cent. of deaths. It may be taken as almost certain that a long time will elapse before this mortality is brought down to 10 per cent. However, if the results, immediate and remote, and as regards control of fæces, are better by the newer method the risks of a higher mortality will be faced by many sufferers cheerfully.

A Clinical Lecture

ON

WHEN TO OPERATE FOR ENLARGED PROSTATE:

WITH A REVIEW OF 600 CASES OF TOTAL ENUCLEATION OF THAT ORGAN.

Delivered at the Medical Graduates' College and Polyclinic on March 17th, 1909,

By P. J. FREYER, M.D., M.CH. R.U.I.,
SURGEON TO ST. PETER'S HOSPITAL; CONSULTING SURGEON TO QUEEN ALEXANDRA'S MILITARY HOSPITAL.

GENTLEMEN,—Nearly eight years have now elapsed since I first brought my operation of total enucleation of the prostate for radical cure of enlargement of that organ to the notice of the profession in a lecture delivered in this college on June 26th, 1901, and published in the *British Medical Journal* of July 20th of the same year. I then gave full details of four instances in which I had performed this operation, in all successfully.

I have now completed 600 cases of this operation, the statistics of which I will presently place before you. But before doing so I propose once more giving you an account of the anatomical and pathological considerations on which the operation is based, and describing the various steps of the operation. Further, I shall endeavour to answer a question that is frequently put to me—one of great importance to you, as general medical practitioners—namely, At what period in the history of this disease is it advisable to have recourse to surgical operative interference?

Let me, in the first instance, however, introduce to you the first two patients on whom I performed this operation of total enucleation of the enlarged prostate. They have been good enough to come here to-day at my request in order that
questioning them and
results of this opera-
ly 79 and 75 years;
eight years and four months having elapsed in the first case and eight years in the second since the operation was performed. They will recount to you the severe sufferings they went through for some years before operation, having been entirely dependent on the catheter, and their complete freedom from urinary symptoms and excellent health enjoyed by them since recovery therefrom. No catheter or instrument of any kind has been employed since then, and they will tell you that they can retain and pass urine which is perfectly normal not only as well as, but even better than, at any previous period in their histories, for the stream flows in larger volume and with greater force than before They will further tell you that they regained sexual power after

having lost it temporarily in consequence of the pain and debility attendant on the malady. The term "success" after surgical operations is capable of very elastic interpretation. In these cases you will observe that success signifies an absolute and complete cure.

Another of the four cases detailed in my first lecture wrote on Jan. 5th, 1908: "From the day I left the home up to the present time I have never suffered the slightest pain or inconvenience in any way, and I feel now ten years younger than when I first, so fortunately for me, met you." This gentleman paid me a friendly visit about a week ago, when I found him—nearly eight years after operation—in perfect health, untroubled by any urinary symptom. The fourth case, a hospital one, I lost touch with some months after the operation, and have since been unable to trace him owing to change of his address. During those months he suffered from no urinary symptom.

[Mr. Freyer then described the anatomical and pathological considerations on which the operation is based, as well as the various steps of the operation. For these the reader is referred to THE LANCET of July 23rd, 1904.[1] They are given more fully still in the third edition of Mr. Freyer's work "Enlargement of the Prostate."[2]]

Passing on now to the question as to what period in the history of prostatic enlargement it is advisable to have recourse to surgical interference in the form of operation, apart from the patient's age and general state of health, the two following considerations have to be taken into account: (1) The specific symptoms dependent on the prostatic enlargement from which at the time the patient is suffering; and (2) the nature, size, and general conformation of the prostatic growth.

I. Patients suffering from prostatic symptoms will be found when they apply for surgical relief to come under one or other of the following types: 1. Patients suffering the usual symptoms of prostatic enlargement in the earlier stages of the malady, in whom on examination not more than an ounce or two of residual urine is found on introducing a catheter. 2. Those who have probably suffered from prostatic symptoms for several years, in whom we detect a quantity of residual urine varying from 3 to 10 ounces, or even more, but who have never employed a catheter for the purpose of emptying the bladder. 3. Patients suffering from over-distension of the bladder, with extreme frequency of micturition, possibly continuous dribbling of urine, particularly at night time when asleep, but who have never been relieved by a catheter. These patients invariably consult the surgeon because, as they say, they "cannot hold their water," little imagining that the bladder is over-distended and that it is the "overflow" which dribbles away. They are intensely astonished when you draw off several pints of urine by the catheter, with a corresponding decrease in the size of the abdomen. 4. Those cases in which the conditions described in paragraph 3 have culminated recently in complete retention of urine, and in whom great difficulty is experienced in introducing a catheter. 5. Patients who from time to time have had retention of urine, which was relieved by the catheter, but who have not employed this instrument as a routine practice to empty the bladder daily. 6. Patients who for weeks, months, or even years have employed the catheter daily, once, twice, or oftener, for emptying the bladder, but who still retain the power of passing a certain quantity of urine naturally. 7. Those entirely dependent on the catheter for emptying the bladder. In the advanced stages of the disease patients of this type rarely escape from recurrent attacks of one or more of the following complications—viz., cystitis, pyelitis, hæmorrhage, vesical calculus, recurrent attacks of fever with rigors, and difficulty in introducing the catheter.

In the first of these types it will, as a rule, be unnecessary and inadvisable to attempt the removal of the prostate; because, in the first place, the symptoms will probably not be sufficiently irksome to warrant such an operation; and, secondly, the enlargement of the organ will not have sufficiently advanced to render it prominent in the bladder, or to define adequately the lines of cleavage between the true capsule and the enveloping sheath. But in one and all of the other types the removal of the prostate should be entertained and advocated if on examination it presents those characteristics—to be presently described—that render its enucleation entire in its capsule practicable, there being no condition of the general health of the patient to negative an operation of this magnitude.

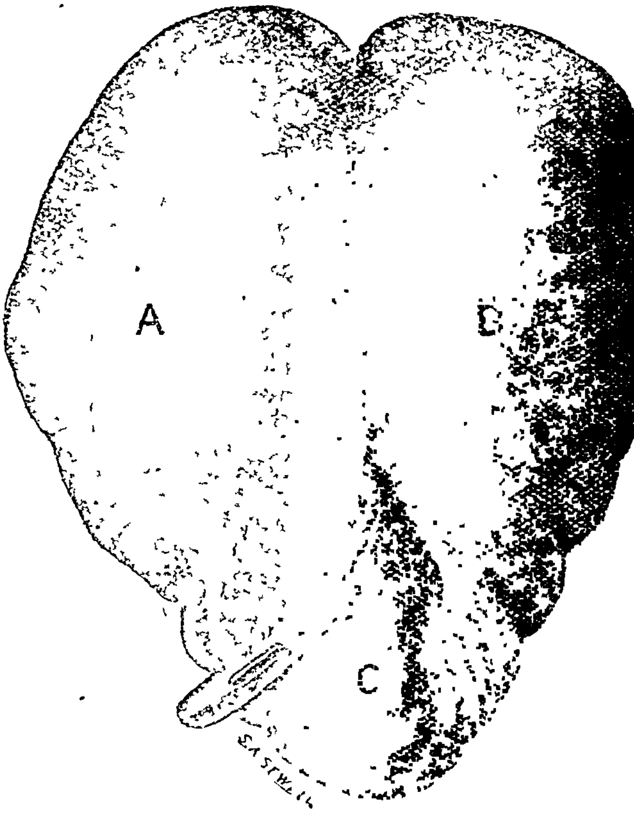
Prostate weighing 1¾ ounces, removed from a patient aged 67 years (Case 133) A, Left lobe B, Right lobe. The catheter shows the position of the prostatic urethra

FIG 2



Prostate weighing 6¾ ounces, removed from a patient aged 62 years (Case 112) A, Left lobe B, Right lobe, giving off an out-growth, C, in the bladder. The catheter shows the tortuous course of the urethra

I cannot too strongly urge early removal of the prostate when there is decided enlargement of this organ, giving rise to urgent symptoms necessitating the employment of the catheter, [illegible] is practically no danger attaching to the operation in experienced hands. But when once complications set in, and particularly when the kidneys become diseased, whether through backward pressure of the urine on these organs or from extension upwards of inflammation from the bladder, the operation must necessarily be attended by considerable risk.

---

[1] 110 Cases of Total Enucleation of the Prostate for Radical Cure of Enlargement of that Organ.

[2] Baillière, Tindall and Cox, London.

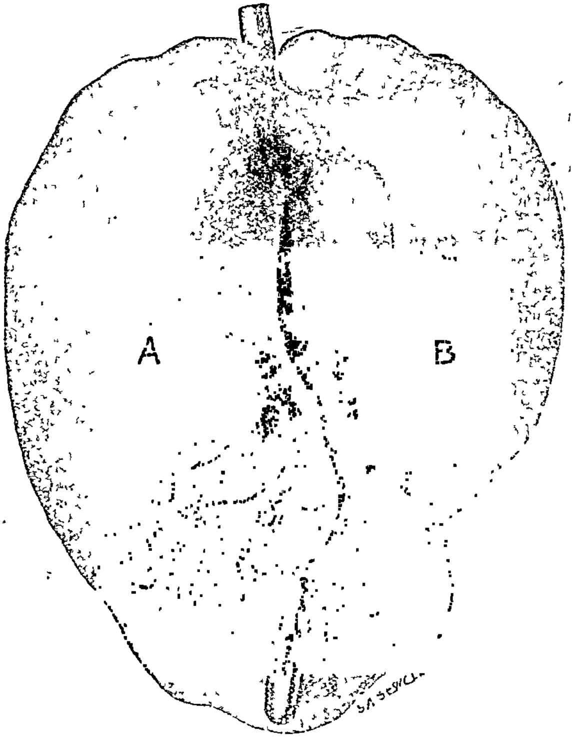
Another grave danger attached to postponement of operation is this, that recent experience has demonstrated beyond doubt that the adenomatously enlarged prostate, which is, of course, a benign growth, has a tendency to assume a cancerous type under the irritating influence of the catheter and complications incidental to catheter life. This is a subject to which considerable attention has been directed recently in France, and so experienced and practical a surgeon as Pauchet of Amiens puts the proportion of adenomatous prostates that thus degenerate at as high a figure as 10 per cent.

II. In order to ascertain whether the prostate is capable of being enucleated entire in its capsule, the patient, if capable of passing any urine naturally, is directed to empty his bladder as far as possible, and is then placed on a couch in the recumbent position. The bladder is then emptied of its residual urine by means of a catheter. The forefinger of one hand, previously lubricated, is slowly introduced into the rectum, and when the sphincter ani is thoroughly relaxed a survey of the rectal aspect of the prostate is made If the organ is found to be decidedly enlarged, presenting a well-marked tumour in the rectum, more or less rounded in shape, bilobed laterally, with a well-marked furrow in the median line, smooth on the surface, soft or somewhat dense to the touch, and (most important of all) moveable, you know that you have to deal with the ordinary adenomatous enlargement of the gland of advanced life. If, in addition, from its prominence in the rectum you estimate the tumour to be at least of the size of a Tangerine orange, the case may be regarded as in all probability one in which the prostate is capable of being enucleated entire.

We next proceed to make a bimanual examination of the [illegible] the fingers of the [illegible] essing them well [illegible] time directing the patient to relax the abdominal muscles. Counter-pressure is made by the finger in the rectum. If the prostate is decidedly enlarged it will be felt between the fingers of the two hands and can be slightly moved upwards, downwards, or from side to side, like a chronically enlarged uterus, but to a less extent. If it be very prominent in the bladder the outgrowth in that viscus will be easily recognised, and in thin subjects the origin of this [illegible] left lobe, or from botl [illegible] ients this method of ex [illegible] nd is most helpful for diagnostic purposes. In very stout subjects it is less satisfactory. Occasionally we meet with patients who are unable to relax their abdominal muscles; in such cases the examination can only be satisfactorily accomplished under the influence of an anæsthetic.

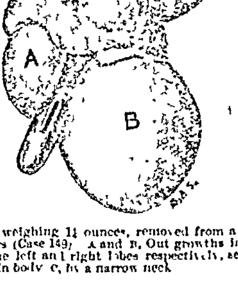
If on bimanual examination the prostate, with the characteristics already described, be felt distinctly, we can at once pronounce the case to be one in which the organ can be enucleated entire in its capsule, no matter what magnitude it may have attained. *Prostates weighing from, say, about*

FIG 3.



Prostate weighing 14¼ ounces, removed from a patient aged 73 years (Case 106) A, Left lobe, showing an ulcer at D, caused by a vesical calculus B, Right lobe, C Saucer shaped lip connecting the lateral lobes and prominent in the bladder.

FIG 4.



Prostate weighing 1¼ ounces, removed from a patient aged 57 years (Case 149) A and B, Out growths in the bladder from the left and right lobes respectively, separated from the main body C, by a narrow neck

2 to 6 ounces (Figs. 1 and 2), such as those I show you, are those most easily and rapidly enucleated. But prostates of larger size can be similarly dealt with, though those attaining to enormous dimensions such as these (Fig. 3) present considerable difficulties, mainly through their being impacted beneath the pubic arch, and to the difficulty experienced in reaching with the finger in the bladder the distal aspects of the growth—those in proximity to the rectum and triangular ligament—to separate the capsule from the enveloping sheath.

Let us now contrast the characteristics of adenomatous enlargement of the prostate, as just described to you, with those of cancer of that organ in a more or less advanced stage. The first feature that will strike you on rectal examination in cases of cancerous enlargement is the intense hardness of the prostate, which is almost invariably of the scirrhous type, though occasionally we find soft boggy patches, due to broken-down tissue. Then the outline of the organ will be irregular, the lobes being ill-defined, and the median groove being partially or wholly obliterated. The organ will be nodular and ridged, with deep, irregular, intervening furrows. Occasionally you will come across a case in which the carcinomatous prostate is smooth and globular, like an ivory ball. Most important of all for diagnostic purposes, the prostate will be immoveably fixed in the pelvis owing to the invasion by the growth of the adjacent tissues. Bimanual examination will confirm the existence of these characteristics, particularly the immobility of the organ, but as a rule in cancer of the prostate no great prominence of the gland will be felt in the bladder, the growth invading the surrounding tissues rather than advancing into the bladder, the trigone of which is, however, very frequently involved. You will have as additional aids to diagnosis enlargement of the glands in the groins in advanced stages of the malady, and at an earlier stage small, hard, sago-like grains may be felt per rectum covering the surface of the growth beneath the rectal mucous membrane. These are secondary deposits in the lymphatics coursing in the sheath of the prostate. Then, in the clinical history of the case you will have the rather sudden onset and rapid advance of the usual prostatic symptoms, the progressive and sometimes rapid loss of flesh, the feeling of lassitude, debility, and undue fatigue, the failure of appetite, the typical cachexia, and the pains in the loins, sacral region, and lower limbs, due to pressure on the nerves by secondary deposits in the lymphatic glands, so characteristic of this disease. It is impossible to enucleate a cancerous prostate in this advanced stage, owing to the extension of the disease to the surrounding tissues In the earlier stages of the malady, however, whilst the prostate is still moveable and the adjacent structures uninvolved, the gland can, and should be, removed. My experience of operation under such circumstances is most favourable. It is frequently impossible, however, to give a definite diagnosis of malignancy before removal of the gland in cases of this kind, though the presence of dense nodules in the prostate, combined with the rapid march of the symptoms, will arouse grave suspicions in the surgeon's mind as to the true character of the disease.

It is, however, when we have to deal with adenomatous enlargements of the prostate of smaller dimensions—say, less than 1½ ounces in weight (Fig. 4)—that the greatest difficulties present themselves as to the possibility of their enucleation entire being practicable. For I may tell you, as the records of my published cases show, that you may find complete dependence on the catheter, strange as it may appear, with a prostate weighing 1½ ounces, 1 ounce, or even less. A prostate of 1 ounce in weight will scarcely feel enlarged per rectum, or even bimanually, unless the patient be very thin. The only way we can determine with certainty the possibility of enucleating a prostate of this size is by the aid of the cystoscope. If on cystoscopic examination we find that there is a well-defined out-growth of one lobe, or marked prominence of both lobes (Fig. 4), in the bladder, the case may be pronounced to be one permitting of enucleation of the gland entire, no matter what its size may be as felt per rectum.

Results from the Operation.

I have now completed 600 cases of the operation of total enucleation of the prostate for enlargement of that organ, the patients varying in age from 48 to 89 years, with an average age of 68½ years. There were 47 octogenarians between the ages of 80 and 89, and 7 patients aged 79 years. The prostates ranged from ½ to 16¾ ounces, with an average weight of about 2½ ounces. The great majority of the patients had been entirely dependent on the catheter for periods varying up to 24 years. Nearly all were in broken health and many apparently dying before operation. Existence was simply intolerable to most of them. Few were free from one or more grave complications, such as cystitis, stone in the bladder, pyelitis, kidney disease, diabetes, heart disease, chronic bronchitis, paralysis, hernia, and in a few instances there was malignant disease of some other organ than the prostate. Such were the unfavourable circumstances under which the operation was undertaken.

In connexion with these 600 operations there were 37 deaths, in periods ranging from six hours to 37 days after the operation, or a mortality of 6·15 per cent. The mortality has been steadily decreasing from 10 per cent. in the first 100 cases to 4 per cent. in the last. The causes of death were: uræmic symptoms due to chronic kidney disease, 16; heart failure, 6; septicæmia, 2; shock, 3; exhaustion (kidneys much diseased), 1; mania (hereditary in 1), 2; malignant disease of liver, 2; heat stroke, 1; pneumonia, 1; acute bronchitis, 1; pulmonary embolism, 1; and cerebral hæmorrhage with paralysis, 1. Though all these deaths are accepted in connexion with the operation, in not more than half the number can the fatal result be attributed thereto, the remaining deaths being due to disease incident to old age and unconnected with the operation. In 108 cases vesical calculi were removed at the same time; but all the deaths in these cases are accepted in connexion with the prostatectomy, none being put down to the suprapubic lithotomy involved.

When I speak of success attending the operation I mean an absolute and complete success as in the two cases brought before you to-day, the patient regaining the power of retaining and passing his urine naturally, without the aid of a catheter as well as he ever did. There is no relapse of the symptoms, no contraction at the seat of operation leading to stricture and no fistula remaining. Further, there is no diminution in the sexual power after the operation.

ON THE

DISCRIMINATION OF UNRECOGNISED DISEASES AND ON A DISEASE OF OVERCROWDING IN SHIPS, ESPECIALLY AT MALTA.[1]

By W. E. HOME, B.Sc., M.D. Edin., M.R.C.P. Edin., D.P.H.,

FLEET SURGEON, R.N.; FORMERLY SENIOR MEDICAL OFFICER IN THE CHANNEL FLEET.

It is sometimes interesting to take a famous book by one of the old masters of medicine and read in it to see whether it may not still have some lesson for us now. What books of these survive were written by very capable men; that is why they have not been forgotten, and the talent which these elders brought to the study and solution of their problems will often show us a good method for attacking ours of to-day.

The classics in my branch of the profession are Pringle, Lind, and Blane. Sir John Pringle (1707–82), physician-general to the forces, and later president of the Royal Society, in 1752 brought out his great work on *the* "Diseases of the Army." He was the "founder of Military Medicine" (J. F. Payne), the first to prevent dysentery and hospital fever. James Lind (1716–94), for 35 years in charge of Haslar Hospital, proved the usefulness at sea of distilled water and of lime juice to prevent scurvy; 1754, "Treatise on Scurvy"; 1757, "Health of Seamen." Sir Gilbert Blane (1749–1834) went to the West Indies as Lord Rodney's private physician, but, winning the admiral's good opinion by professional skill and personal bravery, was made physician to the fleet. He got lime juice made an issue, which Lind had never achieved, and I believe it was his representations that got a uniform established for our sailors to prevent typhus fever. In 1786 he published "The Health of Seamen."

---

[1] A paper read before the Epidemiological Section of the Royal Society of Medicine on March 26th, 1909.

In the natural history of those days the classification of animals and plants was artificial; not enough knowledge had yet been acquired to make a natural system possible. And it was the same with the diseases. An etiological classification, such as we attempt to-day, was unattainable; all the differentiation they had was clinical, by signs or symptoms, or by the regions or organs attacked.

Pringle knew intermittents, diagnosed pneumonia, pleurisy, and consumption; the other diseases which he reports from his field hospital in the spring of 1743 are: rheumatic pains, with more or less fever; inflammatory fever, without rheumatic or pleuritic pain; hard coughs without fever; fluxes; some inflammatory symptoms. "Fevers" were the most numerously occurring of all diseases. Lind reports that 2174 cases were admitted to Haslar Hospital in two years (1758–60)—38 per cent. of all admissions. Blane reports 806 cases in Rodney's fleet in 1782—44 per cent. of all cases added to the sick list. The exanthemata were not included, but even so the class of "fevers" was so large that it had to be broken up somehow, and with the knowledge which they had they could only group their cases by the time and place of their occurrence. Thus Pringle and Francis Home, my great-grandfather, who both served with the army in the Low Countries in 1740 onwards, and both wrote books about their service—books which are in the society's library—grouped the fevers year by year for descriptive purposes (fever of 1741, fever of 1742, &c.), and Blane in the West Indies follows quite the same method.

I submit these facts to this section, whose study is the natural history of disease with a view to its prevention, that it may be realised why prevention in those days lagged so behind. It is difficult to form a consistent theory of the cause of a single disease—how impossible to analyse the causes of a mixed assortment of diseases—and I desire to simply restate what everyone here knows, that a good classification of diseases is a great help towards prevention. As we now know that phthisis, lupus, and tubercular meningitis are not separate diseases but only separate evidences of the same *noxà*—the tubercle bacillus—a case of either reinforces the demand for the prevention also of the other, as the harmonics strengthen the fundamental note in a chord.

Now from that great mass of fevers which the old observers report there have been extracted and identified several groups—malarial remittent, for example. 70 years ago typhus and typhoid fever were discriminated after long search; Bruce lately extricated the Malta fever conveyed by goat's milk, and there are others; but we who go abroad still find cases to which we cannot satisfactorily apply the names we see in the text-books, fevers for which we do not know the cause.

It was a great advance to separate typhoid from typhus fever; difficult clinically, and for two reasons. Unlike other diseases, which, similar at first, seem to differentiate themselves as they progress, these two fevers end in a very similar typhoid condition. This they were particularly apt to do in the olden days, when, as you will remember, patients in fever hospitals had only 600 cubic feet of space. Ventilation was thought harmful, and venesection must, one thinks, have caused all patients to present after long illnesses a similarly exhausted appearance. There was another and a greater difficulty. These fevers were apt to occur in different places each by itself, and as communications were less free and frequent then than now authors may not have seen them both. I have always been told that in the "thirties" of last century there was animated controversy between the [illegible]y and [illegible] or at [illegible]ight, *though each saw only his own side of the shield*; "fever" in Edinburgh was typhus, "fever" in Paris was typhoid. That neither of them would give in did both schools credit, for so we came to know the truth.

This raking amongst the embers of forgotten controversies will be of benefit to us if it makes us reflect and inquire whether such controversies are not going on amongst us now. Is it at all possible that among the less well-known and unnamed fevers of to-day there are not some as distinct as those others, which too, when discriminated, might be in their turn prevented? Public health has so greatly improved that we can expect no so marked results as followed the recognition of typhus and its subsequent prevention. Still, it may be worth our while to seek out and differentiate these others that in time, as I say, they may be stopped. It is a little novel this idea of going to look for a new disease; they are generally discovered more or less by accident. To pick out a new disease is much as if one were in a club where habitually one met some 30 or 40 Englishmen, but one night there appeared a Scotchman, and would one notice him? Essentially different he would be, but in appearance he might be very like an Englishman, or he might be very different. If one had no warning to expect a different sort of stranger one might class him in one's mind with some other member one knew like him, unless he spoke and failed us in English, which would be a sort of Widal reaction to test him.

Each new case as we see it we class with some others we have already seen, unless something very striking shows it to be peculiar, or unless many others suddenly begin arriving far more like one another than like any of those we have known about before. Each of us looks at cases from the point of view to which his own experience has conducted him, and his comparisons may be as different from those of his neighbours as was that of the little town-bred child on her first train journey in the country, who amused us all as we passed some sheep by her excited surprise at the "funny dogs those are." And probably that is how we shall meet a first case of a new disease. It will be "a funny case," "an odd case," an unpaired case that is. It is these odd cases, these residua, that repay investigation. That is how radium was found—in residues. That is how they find gold at the mines.

As to the local assignment of "fever" of which I spoke I was much struck with this in the "nineties" on the East Coast of Africa. Durban fever used to be talked of in the "seventies." In the "nineties" you heard no more of Durban fever. Durban had got settled, had sown, reaped, and was done with its wild oats. A reputation for fever now *attached itself to the ill-built*, untidy, or *sparsely* populated places up the coast—Beira, Chinde, Quilimane. These fevers all seemed to be malarial, but in those days we had no exact diagnostic, and we had advantage from calling these cases by names of the places where they originated, for we never knew when some other fever might appear nor whence—some other fever terrible as the dreaded blackwater fever—and the name it got would be a warning to the newcomer to give that place a wide berth if possible.

In the early "nineties" we classified fevers into (1) zymotic; (2) continued; and (3) malarial (which might be remittent or intermittent). Zymotic in East Africa (except dengue) we did not see, continued meant typhoid, intermittent are a well-marked class, and all other fevers were returned as remittent and ascribed to malaria, or in those days the same thing—climate. The preoccupation of every surgeon on this East African station was "fever"; it was climatic. You could not tell when it would visit your ship or when it would leave. It was climatic, so nothing could be done to prevent it, except keep out of the sun, but it was good to see your ship as clean, dry, and well ventilated as possible, for that increased comfort. When I joined the station I was very anxious about those men, obviously the most exposed to the climate, those who went away in boats cruising after slave dhows, and proposed to my captain I should medically examine them before they started and only allow the healthiest to go. He, however, who had been on the East Coast for a year, laughed at my anxieties and assured me that they were unnecessary. I could not see how this could be if the fever was, as everyone said, due to climate, but I did not press the matter, and I found the captain's view correct, for the fever, after all, was not really due to the climate directly at all.

To anyone reading the reports on the health of the East African station yearly appearing in the Blue-books from 1880 onward it must shortly become evident that within the group remittent fever were included cases of two quite distinct diseases—the first a true malarial remittent, not picked up aboard ship, but always contracted ashore, and generally, almost invariably, by sleeping ashore 10 to 15 days previously. See THE LANCET of Oct. 28th, 1899, where I repeat from the Blue-book for 1887 the history of a party of ten who passed the night ashore. The seven men slept and all got fever; the three officers who did not sleep escaped, for, being always kept awake by the mosquitoes and always brushing them off, they prevented any single mosquito from settling and so infecting them. For this fever quinine was specific. The second fever, on the other hand, appeared to have its origin exclusively in ships; neither in boats, whose crews continuously escaped it, nor ashore; nor did it spread from ship to ship; nor was it carried by wind. It might occur in ships at Zanzibar, but in no relation to the occurrence of fever ashore. In 1880 it was severe on H.M.S. *London*, the stationary ship at Zanzibar, when Zanzibar was healthy. In 1881 it attacked both ships and shore. In 1883 the epidemic in the *London* did not spread to the ships near her, so the infection was not carried, or at any rate did not spread, by wind. Further, it used to be noted that the fever diminished in the *London* when a cool wind blew off shore. In 1887 there was a bad season ashore, but ships suffered little. In 1884 it was reported from the *Euryalus* at Massowah, when it specially attacked the boys. She was described at the time as overcrowded, and those of her ship's company who were landed in Massowah were healthier than those who remained aboard, so it was not Massowah which gave it to them. This fever did not attack the natives serving on board ships, and it was noted to be specially prevalent at Zanzibar during the great rains in the first quarter of the year, both of which facts were held to prove its climatic origin. My view is that it was due to want of ventilation and overcrowding in the ship herself. It occurred in damp ships like the *London*, which was so full of rotten timbers that she was broken up in 1884. It occurred in the great rains; it occurred in ships which, with full complement, had been quite unnoticeably healthy in harbour but were sent to sea in bad weather, for in each case ventilation was impaired. In Zanzibar harbour in dry weather every port and scuttle is wide open and the awning, high up and horizontal, allows air to escape from the ship as freely as possible. At sea in bad weather the scuttles, &c., are closed, and in harbour during the great rains ports are half closed and the awnings sloped, imprisoning the air inside the ship. I did not know all this in 1895. I wish I had. That the natives escaped it too does not prove it was due to the climate. They had far more fresh air than any white man—they lived on the booms, a sort of flying deck above the upper deck, out in the open air—and this may equally explain their immunity, and now you see why the men away in boats escaped. Every now and then one of them would sleep ashore and get malarial fever, but more fortunate than their envied neighbours, with all the comforts of a ship, who with these also had the risk of infection, the boats' crews were thoroughly exposed to the climate and so remained healthy.

The fever of which I am speaking may be described as an asthenic pyrexia without special features. After two days' malaise and headache the patient would get nausea, retching, and vomiting; temperature 101° or 102° F.; pulse about 100; skin moist; bowels confined; headache, pain in loins, and sometimes even already marked exhaustion. Stage of advance: Temperature 103° to 105°; skin dry, often pungently hot; eyes suffused, headache, restlessness, perhaps delirium; tongue dry, thirst, anorexia, perhaps much vomiting; bowels confined; pulse and respiration fast; symptoms worse at night. We thought that this proved the fever to be, as we called it, remittent. I nowadays often wonder if it was due to the diminished ventilation, due to the stillness, the airlessness of a tropical night. Convalescence: Great debility, skin clammy; appetite slowly returned. Complications: Hæmaturia reported by one medical officer; I have known it followed by insanity; definite and routine sequelæ there were none; duration ten days, and relapses may occur. Treatment: Quinine is a good tonic but no specific.
